Next Steps

References

- Telesca et al. (2012) extends Telesca and Inoue (2008) by applying the methods of Telesca and Inoue (2008) to a study of individual age-crime curves in the context of marijuana use over the course of young adulthood

- Representative of criminal career trajectories
- Used to study:
  - Age of onset of offending
  - Timing of peak offending
  - Duration of criminal careers
  - “Types” of criminal careers
  - Other features of criminal careers
- When combined with individual characteristics, can also be used to describe relationship between individual characteristics and features of criminal careers

Next Steps

References

- Relatively new field of statistics
- The same/similar methods referred to as curve registration, warping regression models, structural averaging ...
- Useful when:
  - Data is observed as a time series for many individuals
  - Features of the time-outcome relationship (peaks, inflection points) are of interest
  - Substantial variation in individual curves

Alternative Approaches

Alternative Approaches

Approach of Telesca et al. (2012)

Next Steps

References

- Formulation used by Telesca et al. (2012) introduced in Ramsay and Li (1998)
- Introduces model where
  - All individuals share a stochastic time-response function
  - Variation in observed time-response curves is generated by individual, strictly monotonic functions mapping time to stochastic time, called “warping functions” and noise
    - Flexibility in modeling warping functions obtained by using B-spline basis functions
    - Smoothness of estimated warping functions obtained by penalization of relative curvature

(2012)

Next Steps

References

- Telesca and Inoue (2008) developed a Bayesian framework for functional data analysis based on Ramsay and Li (1998)
  - Allows information to be shared across curves
  - Introduces a temporal misalignment window
  - Incorporates smoothing penalty directly into the model
  - Gives a formal account of amplitude and phase variability
  - Allows for exact inference

- Telesca et al. (2012) is an extension of Telesca and Inoue (2008)
  - Extends the curve registration models, developed for continuous data, to count data
  - Allows scale and time-transformations to depend on individual covariates

Model allows us to explicitly test:

- Relationship between level of offending and individual characteristics
- Unimodality of age-crime curve
- Relationship between phase shift and individual characteristics

- Better familiarity with relevant concepts in foundational papers:
  - Ramsay and Li (1998)
  - Lang and Brezger (2004)
  - Telesca and Inoue (2008)
- Work through derivations of:
  - Posterior predictive loss for Poisson case
  - Conditional posterior distributions of parameters
  - MCMC algorithm used
- Begin working through code
