# Classification

## Bayesian Classifiers

# Bayesian classification

---

- A probabilistic framework for solving classification problems.
  - Used where class assignment is not deterministic, i.e. a particular set of attribute values will sometimes be associated with one class, sometimes with another.
  - Requires estimation of posterior probability for each class, given a set of attribute values:
$$p(C_i | x_1, x_2, \dots, x_n) \quad \text{for each class } C_i$$
  - Then use decision theory to make predictions for a new sample  $\mathbf{x}$

# Bayesian classification

---

- Conditional probability:

$$p(C | \mathbf{x}) = \frac{p(\mathbf{x}, C)}{p(\mathbf{x})}$$

$$p(\mathbf{x} | C) = \frac{p(\mathbf{x}, C)}{p(C)}$$

- Bayes theorem:

$$p(C | \mathbf{x}) = \frac{p(\mathbf{x} | C) p(C)}{p(\mathbf{x})}$$

Diagram illustrating Bayes theorem with labels:

- likelihood** points to  $p(\mathbf{x} | C)$
- prior probability** points to  $p(C)$
- evidence** points to  $p(\mathbf{x})$
- posterior probability** points to  $p(C | \mathbf{x})$

# Example of Bayes theorem

---

- Given:
  - A doctor knows that meningitis causes stiff neck 50% of the time
  - Prior probability of any patient having meningitis is  $1/50,000$
  - Prior probability of any patient having stiff neck is  $1/20$
- If a patient has stiff neck, what's the probability he/she has meningitis?

$$p(M | S) = \frac{p(S | M)p(M)}{p(S)} = \frac{0.5 \times 1/50000}{1/20} = 0.0002$$

# Bayesian classifiers

---

- Treat each attribute and class label as random variables.
- Given a sample  $\mathbf{x}$  with attributes  $(x_1, x_2, \dots, x_n)$ :
  - Goal is to predict class  $C$ .
  - Specifically, we want to find the value of  $C_i$  that maximizes  $p(C_i | x_1, x_2, \dots, x_n)$ .
- Can we estimate  $p(C_i | x_1, x_2, \dots, x_n)$  directly from data?

# Bayesian classifiers

Approach:

- Compute the posterior probability  $p(C_i | x_1, x_2, \dots, x_n)$  for each value of  $C_i$  using Bayes theorem:

$$p(C_i | x_1, x_2, \dots, x_n) = \frac{p(x_1, x_2, \dots, x_n | C_i) p(C_i)}{p(x_1, x_2, \dots, x_n)}$$

- Choose value of  $C_i$  that maximizes  $p(C_i | x_1, x_2, \dots, x_n)$
- Equivalent to choosing value of  $C_i$  that maximizes  $p(x_1, x_2, \dots, x_n | C_i) p(C_i)$   
(We can ignore denominator – why?)
- Easy to estimate priors  $p(C_i)$  from data. (How?)
- The real challenge: how to estimate  $p(x_1, x_2, \dots, x_n | C_i)$ ?

# Bayesian classifiers

---

- How to estimate  $p(x_1, x_2, \dots, x_n | C_i)$ ?
- In the general case, where the attributes  $x_j$  have dependencies, this requires estimating the full joint distribution  $p(x_1, x_2, \dots, x_n)$  for each class  $C_i$ .
- There is almost never enough data to confidently make such estimates.

# Naïve Bayes classifier

---

- Assume independence among attributes  $x_j$  when class is given:

$$p(x_1, x_2, \dots, x_n | C_i) = p(x_1 | C_i) p(x_2 | C_i) \dots p(x_n | C_i)$$

- Usually straightforward and practical to estimate  $p(x_j | C_i)$  for all  $x_j$  and  $C_i$ .
- New sample is classified to  $C_i$  if

$$p(C_i) \prod p(x_j | C_i)$$

is maximal.

# How to estimate $p(x_j | C_i)$ from data?

Tid	Refund	Marital Status	Taxable Income	Evade
1	Yes	Single	125K	No
2	No	Married	100K	No
3	No	Single	70K	No
4	Yes	Married	120K	No
5	No	Divorced	95K	Yes
6	No	Married	60K	No
7	Yes	Divorced	220K	No
8	No	Single	85K	Yes
9	No	Married	75K	No
10	No	Single	90K	Yes

- Class priors:  
 $p(C_i) = N_i / N$   
 $p(\text{No}) = 7/10$   
 $p(\text{Yes}) = 3/10$

- For discrete attributes:  
 $p(x_j | C_i) = |x_{ji}| / N_i$   
where  $|x_{ji}|$  is number of instances in class  $C_i$  having attribute value  $x_j$

Examples:

$$p(\text{Status} = \text{Married} | \text{No}) = 4/7$$
$$p(\text{Refund} = \text{Yes} | \text{Yes}) = 0$$

# How to estimate $p(x_j | C_i)$ from data?

---

- For continuous attributes:
  - **Discretize** the range into bins
    - ◆ replace with an ordinal attribute
  - **Two-way split:**  $(x_j < v)$  or  $(x_j > v)$ 
    - ◆ replace with a binary attribute
  - **Probability density estimation:**
    - ◆ assume attribute follows some standard parametric probability distribution (usually a Gaussian)
    - ◆ use data to estimate parameters of distribution (e.g. mean and variance)
    - ◆ once distribution is known, can use it to estimate the conditional probability  $p(x_j | C_i)$

# How to estimate $p(x_j | C_i)$ from data?

Tid	Refund	Marital Status	Taxable Income	Evade
1	Yes	Single	125K	No
2	No	Married	100K	No
3	No	Single	70K	No
4	Yes	Married	120K	No
5	No	Divorced	95K	Yes
6	No	Married	60K	No
7	Yes	Divorced	220K	No
8	No	Single	85K	Yes
9	No	Married	75K	No
10	No	Single	90K	Yes

- Gaussian distribution:

$$P(x_j | C_i) = \frac{1}{\sqrt{2\pi\sigma_{ji}^2}} e^{-\frac{(x_j - \mu_{ji})^2}{2\sigma_{ji}^2}}$$

- one for each  $(x_j, C_i)$  pair

- For (Income | Class = No):

- sample mean = 110
- sample variance = 2975

$$p(\text{Income} = 120 | \text{No}) = \frac{1}{\sqrt{2\pi(54.54)}} e^{-\frac{(120-110)^2}{2(2975)}} = 0.0072$$

# Example of using naïve Bayes classifier

Given a Test Record:

$$\mathbf{x} = ( \text{Refund} = \text{No}, \text{Status} = \text{Married}, \text{Income} = 120\text{K} )$$

$$p(\text{Refund} = \text{Yes} \mid \text{No}) = 3/7$$

$$p(\text{Refund} = \text{No} \mid \text{No}) = 4/7$$

$$p(\text{Refund} = \text{Yes} \mid \text{Yes}) = 0/3$$

$$p(\text{Refund} = \text{No} \mid \text{Yes}) = 3/3$$

$$p(\text{Marital Status} = \text{Single} \mid \text{No}) = 2/7$$

$$p(\text{Marital Status} = \text{Divorced} \mid \text{No}) = 1/7$$

$$p(\text{Marital Status} = \text{Married} \mid \text{No}) = 4/7$$

$$p(\text{Marital Status} = \text{Single} \mid \text{Yes}) = 2/3$$

$$p(\text{Marital Status} = \text{Divorced} \mid \text{Yes}) = 1/3$$

$$p(\text{Marital Status} = \text{Married} \mid \text{Yes}) = 0/3$$

For Taxable Income:

If Class = No: sample mean = 110

sample variance = 2975

If Class = Yes: sample mean = 90

sample variance = 25

- $p(\mathbf{x} \mid \text{Class} = \text{No}) = p(\text{Refund} = \text{No} \mid \text{Class} = \text{No})$   
 $\times p(\text{Married} \mid \text{Class} = \text{No})$   
 $\times p(\text{Income} = 120\text{K} \mid \text{Class} = \text{No})$   
 $= 4/7 \times 4/7 \times 0.0072 = 0.0024$
- $p(\mathbf{x} \mid \text{Class} = \text{Yes}) = p(\text{Refund} = \text{No} \mid \text{Class} = \text{Yes})$   
 $\times p(\text{Married} \mid \text{Class} = \text{Yes})$   
 $\times p(\text{Income} = 120\text{K} \mid \text{Class} = \text{Yes})$   
 $= 1 \times 0 \times 1.2 \times 10^{-9} = 0$

$$p(\mathbf{x} \mid \text{No}) p(\text{No}) > p(\mathbf{x} \mid \text{Yes}) p(\text{Yes})$$

therefore  $p(\text{No} \mid \mathbf{x}) > p(\text{Yes} \mid \mathbf{x})$

$\Rightarrow \text{Class} = \text{No}$

# Naïve Bayes classifier

- Problem: if one of the conditional probabilities is zero, then the entire expression becomes zero.
- This is a significant practical problem, especially when training samples are limited.
- Ways to improve probability estimation:

$$\text{Original: } p(x_j | C_i) = \frac{N_{ji}}{N_i}$$

c: number of classes

$$\text{Laplace: } p(x_j | C_i) = \frac{N_{ji} + 1}{N_i + c}$$

p: prior probability

m: parameter

$$\text{m - estimate: } p(x_j | C_i) = \frac{N_{ji} + mp}{N_i + m}$$

# Example of Naïve Bayes classifier

Name	Give Birth	Can Fly	Live in Water	Have Legs	Class

owl	no	yes	no	yes	non-mammals
dolphin	yes	no	yes	no	mammals
eagle	no	yes	no	yes	non-mammals

**X: attributes**

**M: class = mammal**

**N: class = non-mammal**

$$p(X | M) = \frac{6}{7} \times \frac{6}{7} \times \frac{2}{7} \times \frac{2}{7} = 0.06$$

$$p(X | N) = \frac{1}{13} \times \frac{10}{13} \times \frac{3}{13} \times \frac{4}{13} = 0.0042$$

$$p(X | M)p(M) = 0.06 \times \frac{7}{20} = 0.021$$

$$p(X | N)p(N) = 0.004 \times \frac{13}{20} = 0.0027$$

Give Birth	Can Fly	Live in Water	Have Legs	Class
yes	no	yes	no	?

$$p(X | M) p(M) > p(X | N) p(N)$$

=> mammal

# Summary of naïve Bayes

---

- Robust to isolated noise samples.
- Handles missing values by ignoring the sample during probability estimate calculations.
- Robust to irrelevant attributes.
- *NOT* robust to redundant attributes.
  - Independence assumption does not hold in this case.
  - Use other techniques such as Bayesian Belief Networks (BBN).
