

Every
time
I fly
into San
Francisco
I map
the San
Andreas
fault
anew

Where
is the
Seattle
fault?

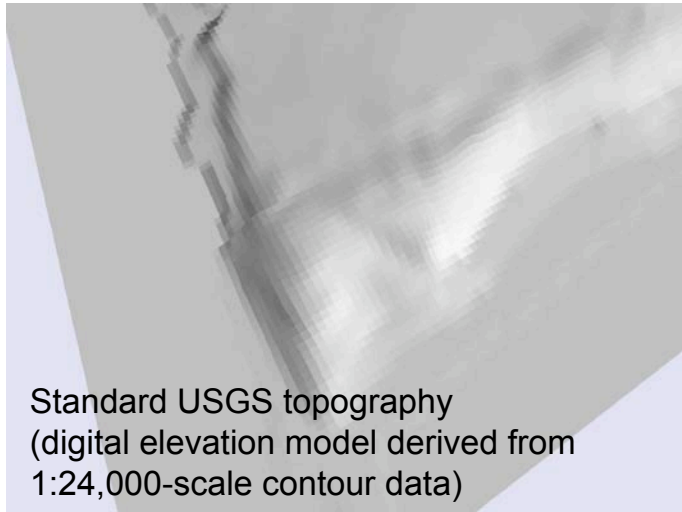

OUTLINE

- How we map topography
- Landscape (the Earth's shape) = History
- The Seattle fault

...via
manual
inter-
pretation
of stereo
aerial
photo-
graphy

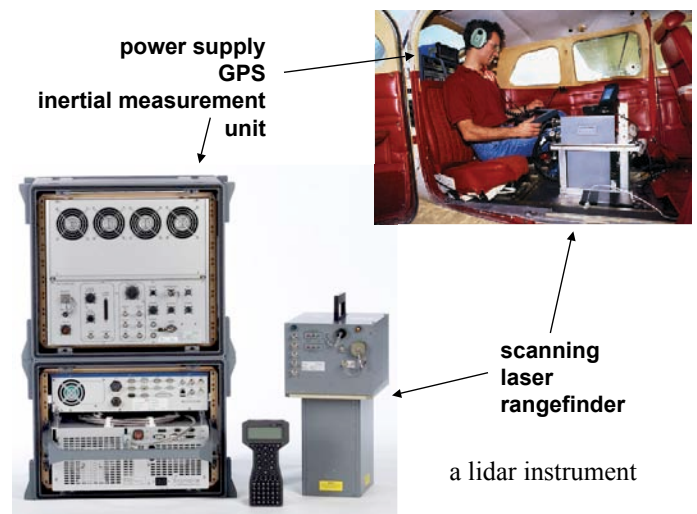

Some problems with contours drawn from stereo photos

- You can't see the ground through the trees
- Sparse sampling. 1:24,000-scale contours have, at best, ~30 meter horizontal resolution
- There is a person involved. Contour topography is subjective!

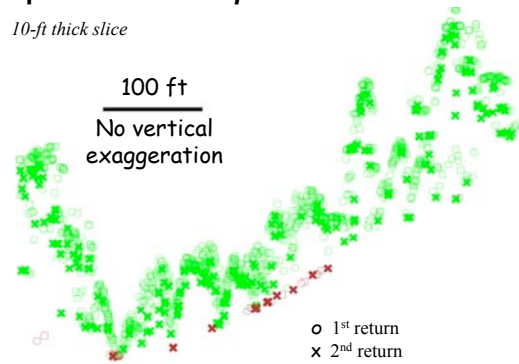

- Differential GPS
- Inertial measurement unit
- Laser rangefinder
- 20,000 to 100,000 pulses per second
- 3-20 million returns per square mile
- 2+ GB per 7.5' quad
- In forested terrain, 4/5 of returns from canopy

A lidar point cloud—pure XYZ position *in profile view*

10-ft thick slice

Despike algorithm

Start with mixed ground and canopy returns (e.g. last-return data), build TIN

Flag points that define spikes (strong convexities)

Rebuild TIN

Flag points that define spikes (strong convexities)

Landscape = History

Topography of the Puget Lowland and environs

Relative to fixed North America:

- Pacific plate moves NW along San Andreas fault
- Sierra Nevada block translates NW
- Basin and Range spreads
- Oregon Coast Range rotates clockwise and translates N
- Washington is squished N-S

Wells and others, 1998

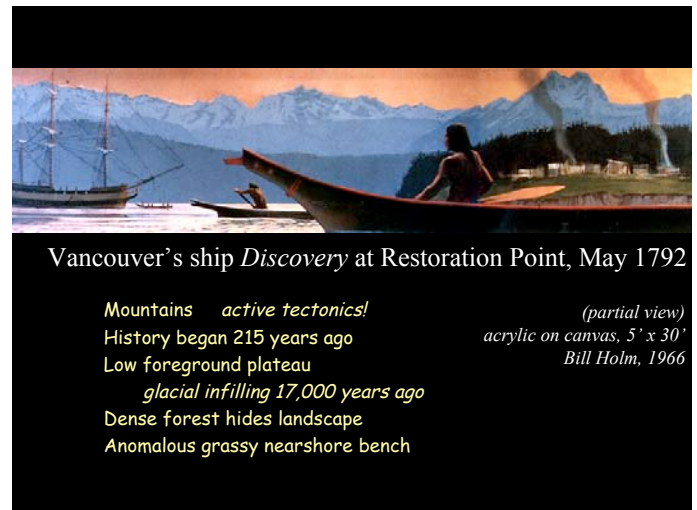

Seattle fault uplift

N-S contraction drives uplift and basin formation

~ 6 km subsidence in 15 million years

*Mountains active tectonics!
History began 215 years ago
Low foreground plateau
glacial infilling 17,000 years ago
Dense forest hides landscape
Anomalous grassy nearshore bench*
