Data

# Geographic Referencing Averaging

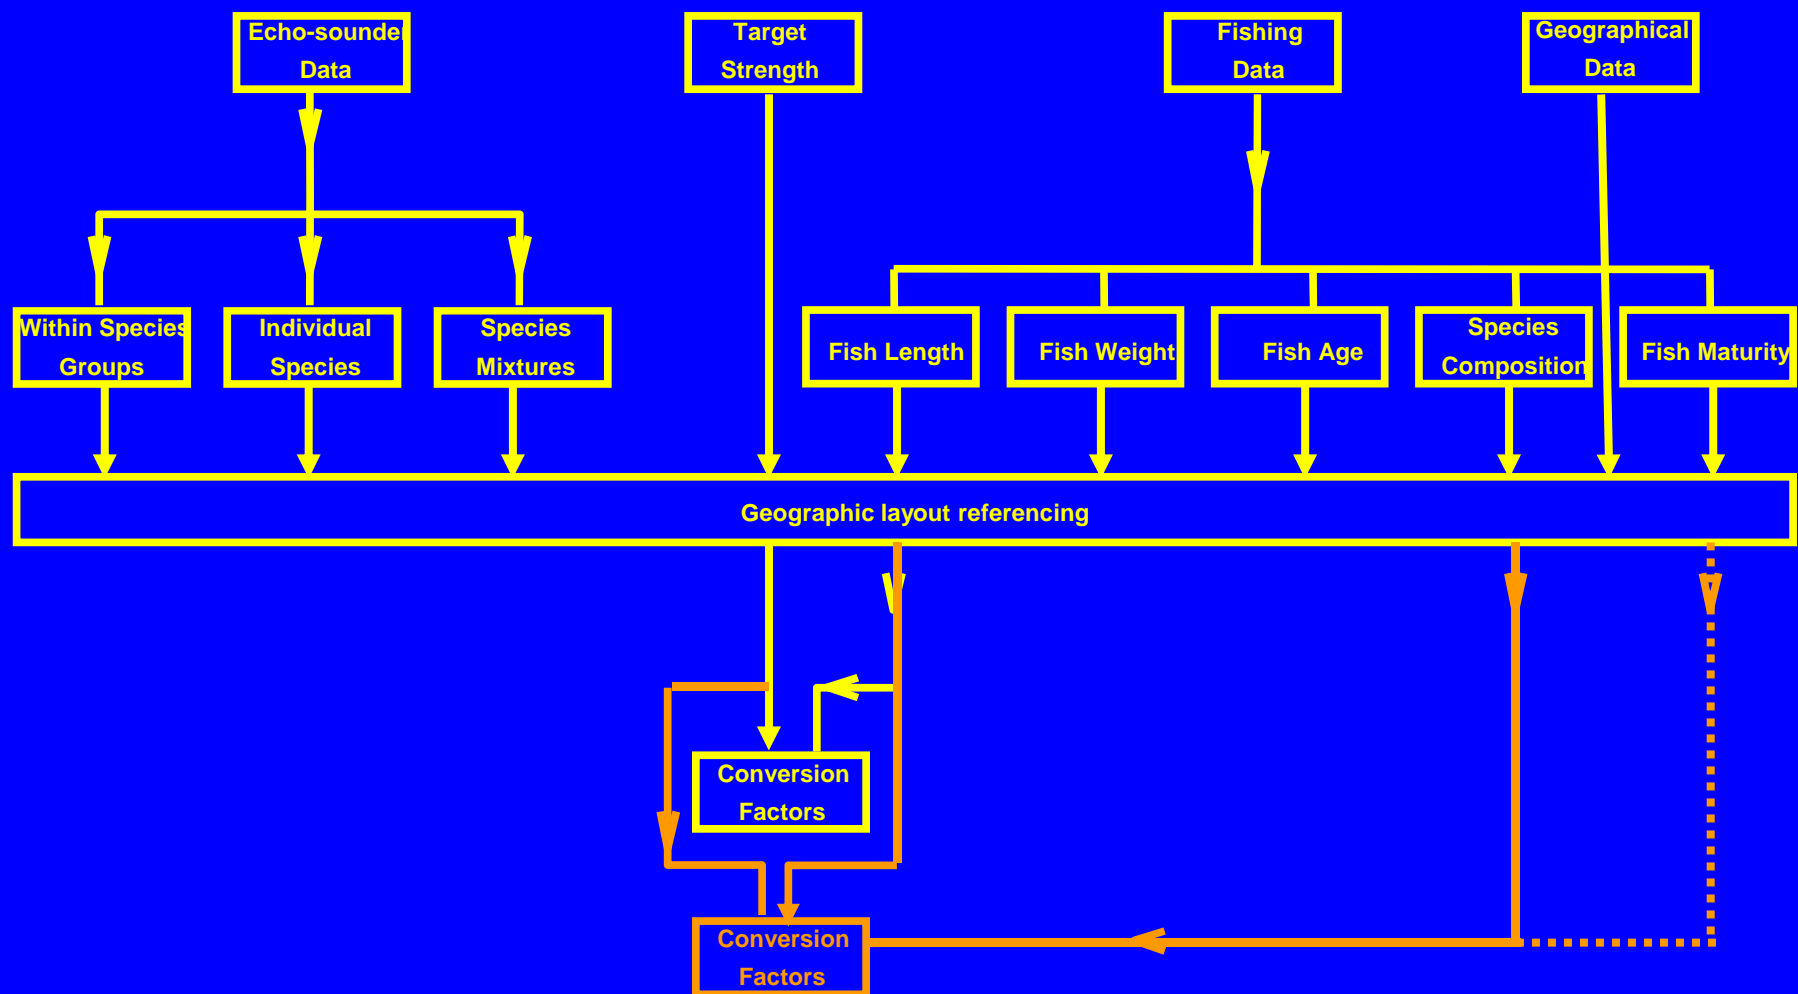

- Weighted sum of parameter values
  - Selection of valid data
- Weighting methods
  - Nearest Neighbour
  - Area / region average
    - Equal weight
    - Weighted by catch rate
    - Weighted by integrator values
  - Kriged estimate
- Externally derived weighing file

# Backscattering Crosssection

- From TS relationships and length
- From TS data
- For multispecies combinations
- Relationships might depend on other biological / distributional factors (e.g. maturity stage / fish depth)

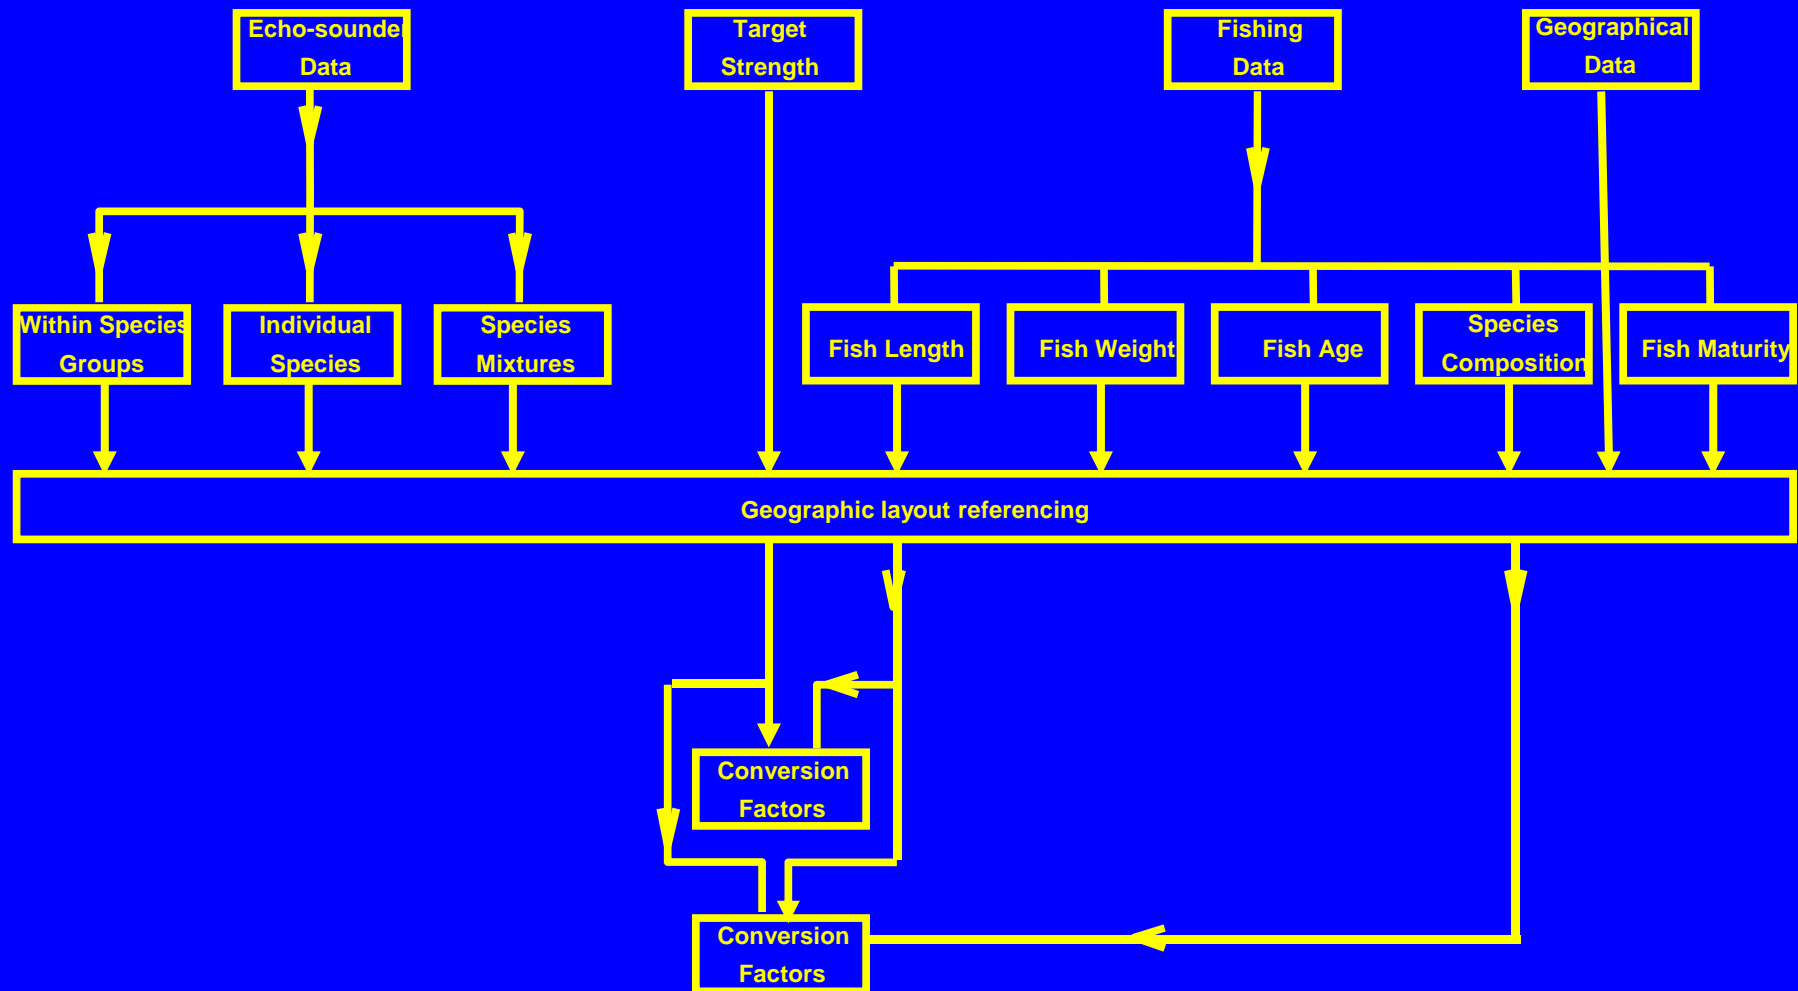

## Calculation of mean Acoustic Cross-section

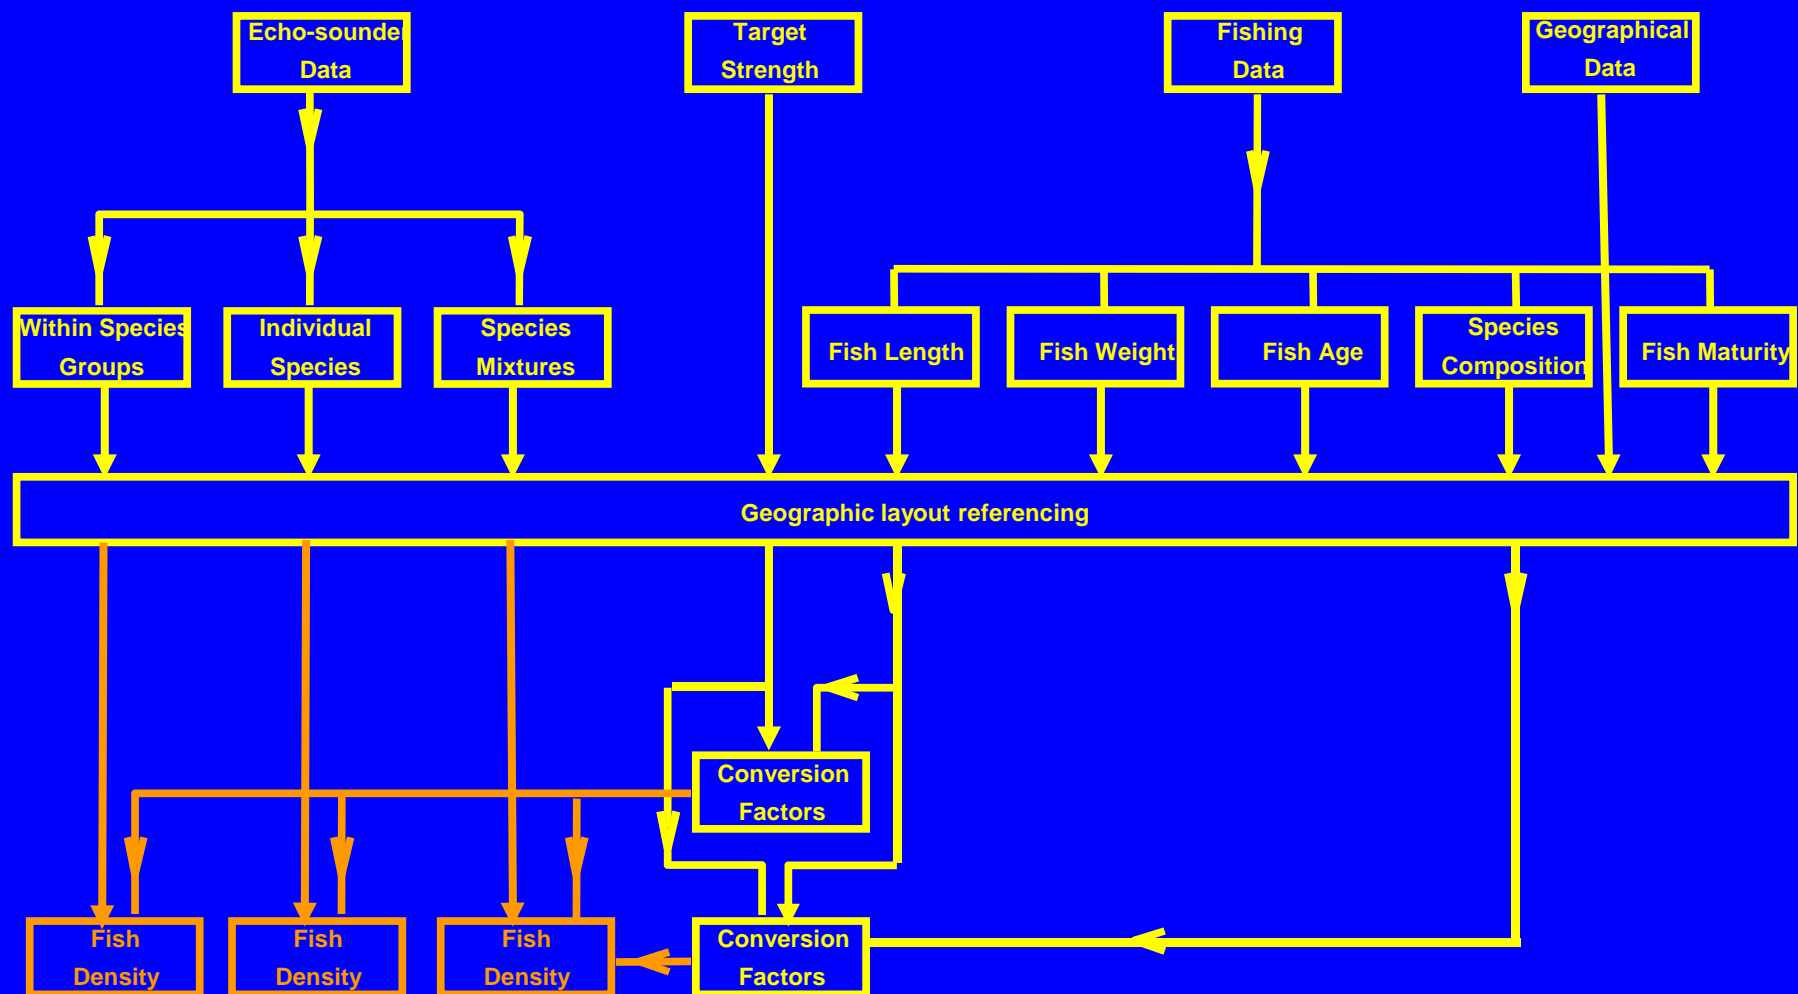

- Single species
  - $TS = a + b \log(L)$
  - $\sigma_{bs} = 10^{\{[a + b \log(L)]/10\}}$
  - Calculate for length distribution  $n_i$  at  $L_i$
  - $\langle \sigma_{bs} \rangle = \sum n_i 10^{\{[a + b \log(L_i)]/10\}} / \sum n_i$
- Combine for multiple species  $j$  with length frequency distribution  $n_{ij}$  at length  $L_{ij}$ 
  - $\langle \sigma_{bs} \rangle = [ \sum n_{ij} 10^{\{[a_j + b_j \log(L_{ij})]/10\}} / \sum n_{ij} ]$
  - Mean TS =  $10 \log \{ \langle \sigma_{bs} \rangle \}$

## Calculation of mean Acoustic Cross-section

- Combine for species  $j$  with length frequency distribution  $n_{ij}$  at length  $L_{ij}$

$$\langle \sigma_{bs} \rangle = [ \sum n_{ij} 10^{\{ [a_j + b_j \log (L_{ij})] / 10 \}} / \sum n_{ij} ]$$

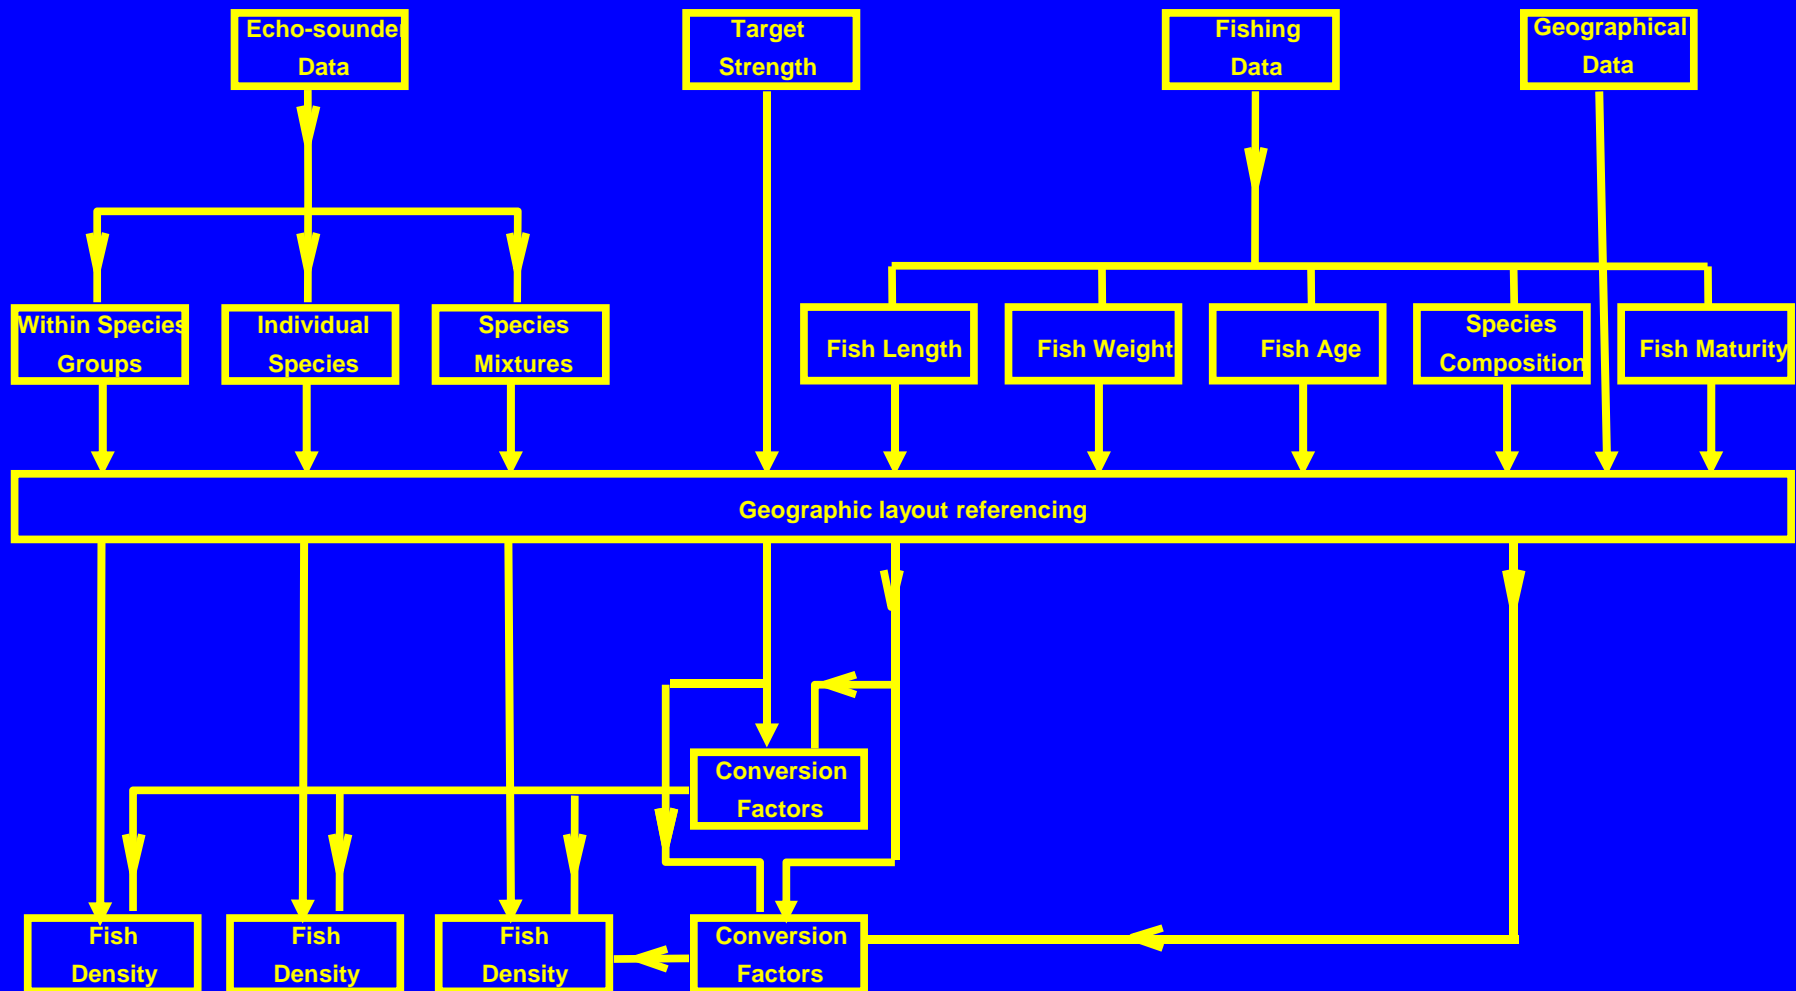

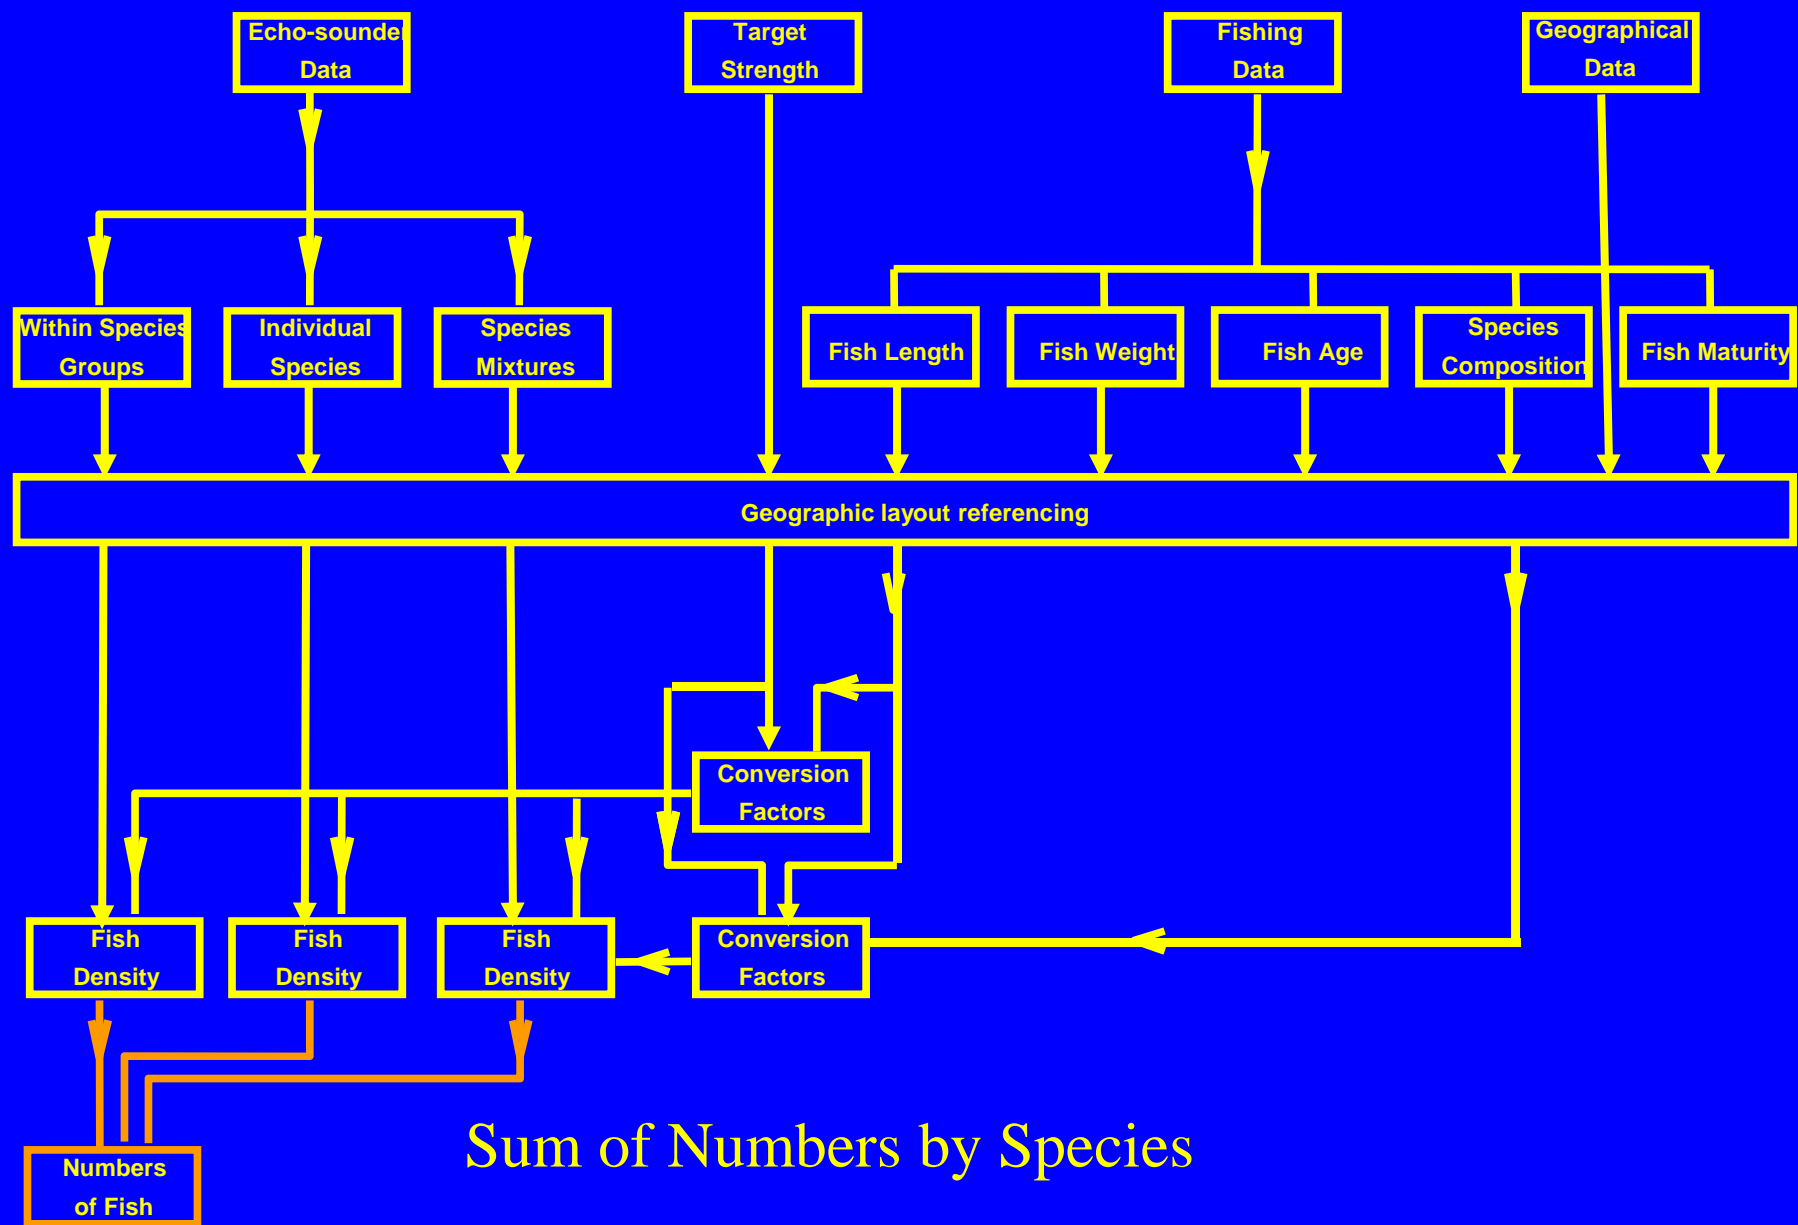

Backscatter \*  $\sigma_{bs}$

# Estimating Abundance

- Density = Echo Integrator Output / Backscattering Cross-section
- Number density  $\rho = s_a / \sigma_{bs}$  (Number  $m^{-2}$ )
- or  $\rho = 10^6 s_a / \sigma_{bs}$  (Number  $km^{-2}$ )
- For EK 60 echosounder  $s_A$
- $s_A = s_a 4\pi 1852^2$
- Then Number density  $\rho = s_A / \sigma_{sp}$  (Number  $N.mi.^{-2}$ )  
where  $\sigma_{sp}$  is the spherical scattering cross section
- or  $\rho = s_A / 4\pi\sigma_{bs}$  (Number  $N.mi.^{-2}$ )
- or  $\rho = s_A / [4\pi\sigma_{bs}(1.852)^2]$  (Number  $km^{-2}$ )
- Requires estimate of  $\sigma_{sp}$  or  $\sigma_{bs}$

Sum of numbers \* mean weights

# Converting Numbers to Biomass

- Biomass = Numbers . mean weight
- $B = N . W$
- if N in millions
- and W in grams
- B is in tonnes
- If N is per unit area B is for the same unit of area
- Weights may be calculated as:
  - Mean weight per fish measured
  - Mean weight using the Length Frequency Distribution and Length/ Weight relationship.

Split by proportions at age / maturity

# Splitting Stock by Age and or Maturity

- For Numbers
  - Multiply Numbers by
  - Fraction at age
  - Fraction mature
- For Biomass at age or maturity
  - Take Numbers at age or maturity
  - Multiply by mean weight at age or maturity stage
- $SSB = \text{Sum of biomass mature fish over all ages}$

# Inclusion of Behaviour effects ?

- TS effects
- Fishing effects

# Output Structure

- Maps
- Regional means
- Documentation
  - Analysis Date / Time Documented
  - Analysis structure / choices

# Summary of analysis

- Obtain echo integrator data for classified categories
- Correct for any calibration errors
- Decide on how area may be partitioned into regions or mapped for single species and multiple species
- Calculate mean length distribution for region
- Calculate  $\langle \sigma_{bs} \rangle$  for each region
- Calculate density (numbers per unit area) from echo integrator output and  $\langle \sigma_{bs} \rangle$
- Calculate area of each region
- Obtain abundance ( Numbers / unit area \* Area )
- Calculate Mean Weights
- Calculate Biomass ( Numbers \* Mean Weight )
- Split by age and/or other biological characteristics
