

Sonar Equation Problem Set #1

Note: Assume sound speed in water is 1500 ms^{-1} .

1) Convert the following levels into decibel units:

- a) $10 \text{ V} = \underline{\hspace{2cm}} \mathbf{20} \underline{\hspace{2cm}} \text{ dB}_v$
- b) $0.1 \text{ V} = \underline{\hspace{2cm}} \mathbf{-20} \underline{\hspace{2cm}} \text{ dB}_v$
- c) $3 \times 10^{-5} \mu\text{Pa} = \underline{\hspace{2cm}} \mathbf{-90.5} \underline{\hspace{2cm}} \text{ dB} \parallel \mu\text{Pa}$
- d) $400 \text{ watts} = \underline{\hspace{2cm}} \mathbf{26} \underline{\hspace{2cm}} \text{ dB} \parallel \text{ watt}$
- e) $0.2 \text{ watts/m}^2 = \underline{\hspace{2cm}} \mathbf{-7} \underline{\hspace{2cm}} \text{ dB} \parallel \text{ watt m}^{-2}$

2) Convert the following levels in dB into the appropriate linear units:

- a) $218 \text{ dB} \parallel \mu\text{Pa} = \underline{\hspace{2cm}} \mathbf{7.94 \times 10^{10}} \underline{\hspace{2cm}} \mu\text{Pa}$
- b) $-12 \text{ dB}_v = \underline{\hspace{2cm}} \mathbf{0.25} \underline{\hspace{2cm}} \text{ V}$
- c) $10 \text{ dB}_v = \underline{\hspace{2cm}} \mathbf{3.16} \underline{\hspace{2cm}} \text{ V}$
- d) $40 \text{ dB} \parallel \text{ watt} = \underline{\hspace{2cm}} \mathbf{10,000} \underline{\hspace{2cm}} \text{ watts}$

3) Estimate the length in meters of a transmitted sound pulse traveling through the water column at pulse durations (or pulse lengths) of 3 ms, 1 ms, and 0.1 ms.

$$\mathbf{3\text{ms} = 4.5 \text{ meters} \quad 1 \text{ ms} = 1.5 \text{ meters} \quad 0.1 \text{ ms} = 0.15 \text{ meters} \quad (c\tau)}$$

4) What is the wavelength in centimeters corresponding to a sound frequency of 38 kHz, 120 kHz, 200 kHz, and 420 KHz?

$$\lambda = c/f = 1500/38,000 \times 100\text{cm/m} = \mathbf{3.95 \text{ cm}}$$

$$\mathbf{120 \text{ kHz} = 1.25 \text{ cm} \quad 200 \text{ kHz} = 0.75 \text{ cm} \quad 420 \text{ kHz} = 0.357 \text{ cm}}$$

- 5) Calculate the number of cycles in each transmission, given the following pulse durations and frequencies.

Pulse Duration	Frequency (f)		
	38 kHz	70 kHz	200 kHz
5 ms	190	350	1000
1 ms	38	70	200
0.2 ms	7.6	14	40

Complete number of cycles/transmission in each cell

- 6) For the three transmitted pulse durations (5, 1 and 0.2 milliseconds) given in Problem #4, estimate the minimum range in meters between two targets that would allow them to be resolved.

$$r = c\tau/2 = (1500 * 0.005)/2 = 3.75 \text{ m}, 1 \text{ ms} = 0.75 \text{ m and } 0.2 \text{ ms} = 0.15 \text{ m}$$

- 7) Given a requirement to resolve targets which are 30 or more cm apart, what is the maximum pulse duration in milliseconds that can be used?

$$\text{Same formula as \#6, solve for } \tau. 0.3 = (1500 * d)/2 \quad \therefore 4E-04 \text{ sec, or } 0.4 \text{ ms}$$

- 8) An echo sounder receives the echo return from the sea bed exactly 0.5 sec after transmission. What is the bottom depth?

$$\text{Travel time} = r/c + r/c = 2r/c \quad 2r/1500 = 0.5 \quad r = (0.5 * 1500)/2 = 375 \text{ m}$$

- 9) Given that we must allow sufficient time for a transmitted echo to return to the transducer before “pinging” again, what is the maximum transmission rate (in pings s^{-1}) at 60 meters depth?

$$\text{Max Ping Rate} = c/2r = 1500/(2*60) = 12.5 \text{ pps}$$

- 10) Based on the nominal transducer beamwidths listed below, calculate the beam diameter (units meters) and the cross-sectional area (units m^2) at each depth (i.e. the “footprint” of the beam).

Nominal Beam Angle	Depth (m)	Beam Diameter (m)	Beam Cross-sectional Area (m^2)
3 degrees	10	0.524	0.216
	50	2.620	5.393
	100	5.241	21.572
	200	10.482	86.286

Nominal Beam Angle	Depth (m)	Beam Diameter (m)	Beam Cross-sectional Area (m^2)
6 degrees	10	1.051	0.868
	50	5.255	21.691
	100	10.510	86.762
	200	21.021	347.049

Nominal Beam Angle	Depth (m)	Beam Diameter (m)	Beam Cross-sectional Area (m^2)
15 degrees	10	2.679	5.639
	50	13.397	140.973
	100	26.795	563.891
	200	53.590	2255.562

11) What is the reduction in the acoustic level of a transmitted signal on the acoustic axis (units decibels) at 100, 200 and 300 m from the transducer?

a) Assuming no other sources of acoustic signal loss other than spreading.

$$TL = 20\log(r) \quad 20\log(100) = 40 \text{ dB}, 200 \text{ m} = 46 \text{ dB}, 300 \text{ m} = 49.54 \text{ dB}$$

b) Assuming an absorption coefficient of 0.1 dB m^{-1} , in addition to the spreading losses.

$$TL = 20\log(r) + \alpha r \quad 20\log(100) + (0.1 \cdot 100) = 50 \text{ dB}, 200 \text{ m} = 66.02 \text{ dB}, 300 \text{ m} = 79.54 \text{ dB}$$
