Overview

• Psycholinguistics and grammar design
  • What grammar has to say
  • What psychological evidence has to say
    • Acquisition
    • Production
    • Comprehension
• Universals
What does grammar have to do with psychology?

Three ways it could be relevant:

- It provides insight into how children acquire language.
- It provides insight into how speakers produce utterances.
- It provides insight into how listeners understand utterances.
Our model: Key characteristics

- Surface-oriented
- Constraint-based
- Lexicalist
Chomsky’s position:

- Grammar represents knowledge of language (“competence”).
- This is distinct from use of language (“performance”).
- We can draw a strong conclusion about language acquisition, namely, most grammatical knowledge is innate and task-specific.
- Serious study of language use (production and comprehension) depends on having a well-developed theory of competence.
Brief remarks on language acquisition

- Chomsky’s nativism is very controversial
  - It is based on the “poverty of the stimulus” argument, and a model of learning as hypothesis testing.
  - The environment may be more informative than he assumes.
  - There may be more powerful learning methods than he assumes.
- There has not been much work on language acquisition using constraint-based lexicalist theories like ours; **but**
  - Explicit formulation is a prerequisite for testing learning models
  - Our feature structures could model richer context information.
- We’re neutral with respect to this controversy.
Production and Grammar

• Evidence for left-to-right effects
• Evidence for top-down planning
Disfluencies are sensitive to structure:

Repeat rate of *the* varies with position and complexity of the NP it introduces:
Production errors are sensitive to syntactic structure

Agreement errors are more common with PP complements than sentential complements: errors like (2) are significantly more common than errors like (1).

(1) *The claim that the wolves had raised the babies were rejected.

vs.

(2) *The claim about the newborn babies were rejected.
So why?

- Speculation: Clauses are their own agreement domains, so people don’t mistake an NP in a lower clause as a trigger for agreement.

- Original work: Kay Bock (1980s).
Some high-level sentence planning is necessary, too

  
  I have the-dat man who-acc I seen have helped
  “I helped the man I saw”

  
  I have the-acc man who-dat I helped have seen.
  “I saw the man I helped ”

- The choice between *dem* and *den* depends on the choice of verbs several words later.
A production model should allow interaction of top-down and left-to-right information

- Grammar plays a role in production.
- Partial grammatical information should be accessible by the production mechanism as needed.
- This argues against grammatical theories that involve sequential derivations with fixed ordering.
- Our theory of grammar has the requisite flexibility.
Comprehension

• Early work tried to use transformational grammar in modeling comprehension

• The Derivational Theory of Complexity: The psychological complexity of a sentence increases with the number of transformations involved in its derivation.

• Initial results seemed promising, but later work falsified the DTC.
Some relevant quotes

• “The results show a remarkable correlation of amount of memory and number of transformations”
  – Chomsky, 1968

• “[I]nvestigations of DTC…have generally proved equivocal. This argues against the occurrence of grammatical derivations in the computations involved in sentence recognition”
  – Fodor, Bever, & Garrett, 1974
“Experimental investigations of the psychological reality of linguistic structural descriptions have...proved quite successful.”
– Fodor, Bever, & Garrett, 1974

In particular, they concluded that “deep structures” and “surface structures” were psychologically real, but the transformations relating them weren’t.
Early Evidence for the Psychological Reality of Deep Structures

• The proposed DS for (2) had three occurrences of *the detective*, while the proposed DS for (1) had only two:

  (1) *The governor asked the detective to prevent drinking.*
  (2) *The governor asked the detective to cease drinking.*

• In a recall experiment, *detective* was significantly more effective in prompting people to remember (2) than (1)
Typical Problem Cases for the DTC

(1) *Pat swam faster than Chris swam.*
(2) *Pat swam faster than Chris did.*
(3) *Pat swam faster than Chris.*

• The DTC predicts that (1) should be less complex than (2) or (3), because (2) and (3) involve an extra deletion transformation.

• In fact, subjects responded more slowly to (1) than to either (2) or (3).
What should a psychologically real theory of grammar be like?

- The “deep structure” distinctions that are not evident on the surface should be represented.

- The transformational operations relating deep and surface structures should not be part of the theory.

- Our information-rich trees include all of the essential information in the traditional deep structures, but without the transformations.
Jerry Fodor claims the human mind is “modular”

“A module is…an informationally encapsulated computational system -- an inference-making mechanism whose access to background information is constrained by general features of cognitive architecture.”

-- Fodor, 1985

A central issue in psycholinguistics over the past 20 years has been whether language is processed in a modular fashion.
Tanenhaus’s Eye-Tracking Experiments

- Participants wear a device on their heads that makes a videotape showing exactly what they’re looking at.
- They listen to spoken instructions and carry out various tasks.
- They eye-tracking provides evidence of the cognitive activity of participants that can be correlated with the linguistic input.
Non-linguistic visual information affects lexical access

- Participants’ gaze settled on a referent before the word was completed, unless the initial syllable of the word was consistent with more than one object.

- For example, participants’ gaze rested on the pencil after hearing *Pick up the pencil* more slowly when both a pencil and a penny were present.
Non-linguistic visual information affects syntactic processing

- Eye movements showed that people hearing (1) often temporarily misinterpreted \textit{on the towel} as the destination.

(1) \textit{Put the apple on the towel in the box.}

- When \textit{on the towel} helped them choose between two apples, such misparses were significantly less frequent than when there was only one apple.
General Conclusion of Eye-Tracking Studies

- People use whatever information is available as soon as it is useful in interpreting utterances.
- This argues against Fodorian modularity.
- It argues for a model of language in which information is represented in a uniform, order-independent fashion.
Speakers know a great deal about individual words

• Individual lexical items have many idiosyncrasies in where they can occur, and in where they tend to occur.

• For example, the verb *behoove* occurs only with the subject *it* (and only in certain verb forms), and the verb *beware* has only the base form.

• We also know that the transitive use of *walk* is much rarer than the intransitive.
V-NP-NP vs. V-NP-PP Frequency in the *NYT*

- **Tell**: 100%
- **Give**: 75%
- **Show**: 50%
- **Hand**: 25%
- **Fax**: 100%
- **Bring**: 75%
- **Send**: 50%
- **Sell**: 0%

Lexical biases influence processing

• Wasow et al ran a production experiment to test whether ambiguity avoidance would influence speakers’ choice between (1) and (2):
  (1) *They gave Grant’s letters to Lincoln to a museum.*
  (2) *They gave a museum Grant’s letters to Lincoln.*

• Lexical bias of the verbs turned out to be a significant predictor of which form speakers used (and ambiguity avoidance turned out not to be).
Experimental Method

1. Speaker silently reads a sentence:

   A museum in Philadelphia received Grant's letters to Lincoln from the foundation.
2. The sentence disappears from the screen. The listener reads the next question from a list.
3. The speaker answers the listener’s question. The listener chooses the correct response on a list (from two choices).
Experimental Results on Local Ambiguity

- V-NP-PP bias
- V-NP-NP bias

% NP NP

- No potential local ambiguity
- Potential local ambiguity
Reverse ambiguity effect

• Arnold, Wasow, Asudeh & Alrenga 2004 *Journal of Memory & Language*

• Re-ran the experiment with slightly better methodology and found a *stronger* reverse ambiguity effect.
A psychologically real grammar should be lexicalist

- Early generative grammars downplayed the lexicon.
- Now, however, the importance of the lexicon is widely recognized.
- This aspect of grammar has been developed in greater detail in our theory than in any other.
- It would be easy to add frequency information to our lexicon, though there is debate over the wisdom of doing so.
Conclusion

• Grammatical theory should inform and be informed by psycholinguistic experimentation.

• This has happened less than it should have.

• Existing psycholinguistic evidence favors a constraint-based, lexicalist approach (like ours).
Universals?

• P&P (top-down): attempts to relate multiple typological properties to single parameters.

• Grammar Matrix (bottom-up): attempts to describe many languages in a consistent framework and then takes stock of common constraints.
Universals?

- Case constraint
- SHAC
- Binding theory
- Head-complement/-specifier/-modifier
- Head Feature Principle
- Valence Principle
- Semantic Compositionality Principle
- ...

Overview

• Psycholinguistics and grammar design
  • What grammar has to say
  • What psychological evidence has to say
    • Acquisition
    • Production
    • Comprehension
• Universals
Reading Questions

• The chapter talks about the grammar being surface orientated and that speakers and hearers start processing before the end of utterances. Does this mean that we can say that humans process language in a bottom-up direction? If so, what's the use of saying a grammar can be processed in top-down direction when it's faster and more natural to do it bottom-up?
Reading Questions

• Doesn't evidence from neurolinguistics re aphasic patients support modularity? (Because damage in a certain spot can "disable" a module)

• What does HPSG have to say about modularity (e.g., fRMI results showing activity outside the language areas during processing)?

• How is the same grammar used in parsing and generation if people can understand more than they can produc
Reading Questions

• How do we incorporate e.g., the morphological functions into the same grammar for real-time processing?
Reading Questions

• Are there places online that have semi-regular articles like this or just talk about various linguistic advancements, applications, findings, etc?

• HPSG bibliography: hpsg.fu-berlin.de/HPSG-Bib/

• HPSG list: hpsg.stanford.edu/hpsg-l.html

• How does visual input relate to linguistic performance (e.g., foreign languages are easier in person v. over the phone)?
Reading Questions

• If HPSG is the best type of grammar shouldn't it be the only type of grammar?

• Are there any other grammar alternatives out there to compare HPSG to? If so, how do they fare on the topics presented in this chapter?

• What are the general criticisms of HPSG? What do you find are some of their most compelling criticisms?

• Did the model start as a way to model grammar? Or was it conceived to model the human understanding of grammar?
Reading Questions

• How does HPSG compare or fit with cognitive theories of grammar such as Talmy and Jackendoff? It seems that semiotic type feature structures in HPSG are similar to cognitivist categorical theories, at least to some extent. Are there any cognitive-computational models out there?
Reading Questions

• If the information required for ambiguity disambiguation, which in this case is word sense disambiguation, includes valence and SEM information that is codified into the lexicon, how is the parser able to disambiguate in a "better" way than a transformational grammar since, If a grammar is a model of competence and performance, how could one disambiguate lexical entries on the fly, as seems to be posited, without simply using trial and error?
Reading Questions

• Prof. Bender what's your personal view? Does our DNA carry embedded grammar engineering code or the code to generate a grammar machine somewhere inside our brain?

• What about formulaic language beyond idioms? Is HPSG compatible with usage-based views of grammar (e.g., Tomasello's)?
Reading Questions

• Can we make a hierarchy of grammar types where the higher types in the hierarchy are shared across all languages, then some are shared across some languages, then some are language specific?

• Can we think of grammar in terms of parameters, where languages make specific (binary) choices? How are these types of settings handled (e.g. head-initial v. head-final)?
Reading Questions

• How can HPSG grammars handle things like disfluencies and ambiguity (in processing)?

• Experience with simultaneous translation (eng > jpn) suggests need for prediction algorithm in L-to-R processing. Does that exist?

• Any work on humor in compiling? Yes: search humor here http://www.aclweb.org/anthology-new/
