MRS

Ling 567 February 6, 2024

Overview

- MRS
 - Goals, design principles
 - Flat semantics
 - Underspecified quantifier scope
 - Linguistic questions
 - MRS in feature structures
- Lab 5 preview

MRS Preface

- Most of today's lecture covers stuff that is already implemented in the Matrix.
- The goal of this presentation is to increase your understanding of what's already there, and how to have your code interact with it.
- In the near term, you'll need to be able to look at the semantic representations and understand them.
- In later labs, you'll also be working on compositionality.

MRS: Goals

- The design of the MRS formalism answers the following four general goals:
 - Adequate representation of NL semantics
 - Grammatical compatibility
 - Computational tractability
 - Underspecifiability

MRS: Design Principles

- The design of the representations of particular linguistic phenomena follow the following general strategies/design principles
 - Represent all semantic distinctions which are syntactically or morphologically marked
 - Underspecify semantic distinctions which aren't: These can be spelledout/ambiguated if necessary in post-processing
 - Abstract away from non-semantic information (word order, case, ...)
 - Close paraphrases should have comparable or identical MRS representations
 - Aim for consistency across languages
 - Allow for semantic differences across languages

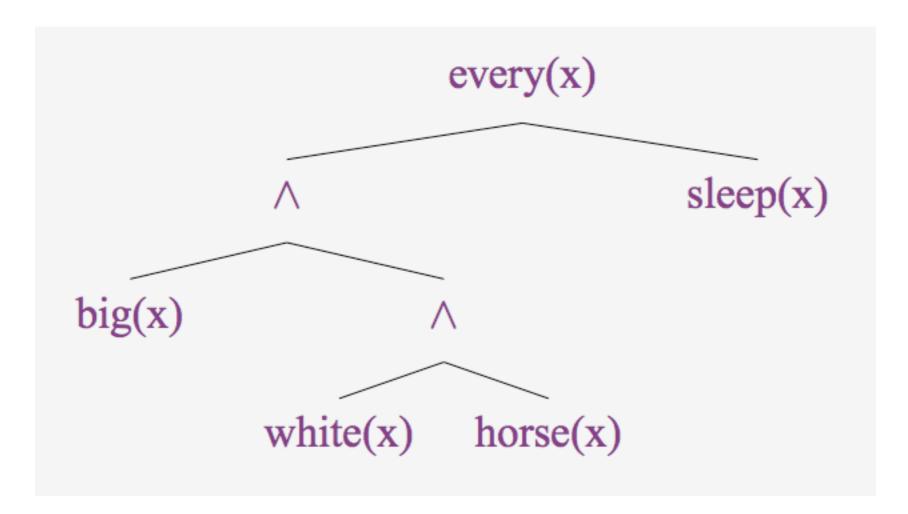

A quick reminder about quantifier scope

- Quantifiers (predicate logic or NL) take three arguments:
 - A variable to bind
 - A restriction
 - A body
- Every dog sleeps: $\forall x \ dog(x) sleep(x)$
- When one quantifier appears within the restriction or body of another, we say the second has wider scope: $\forall x \ dog(x) \ \exists y \ cat(y) \ see(x, y)$

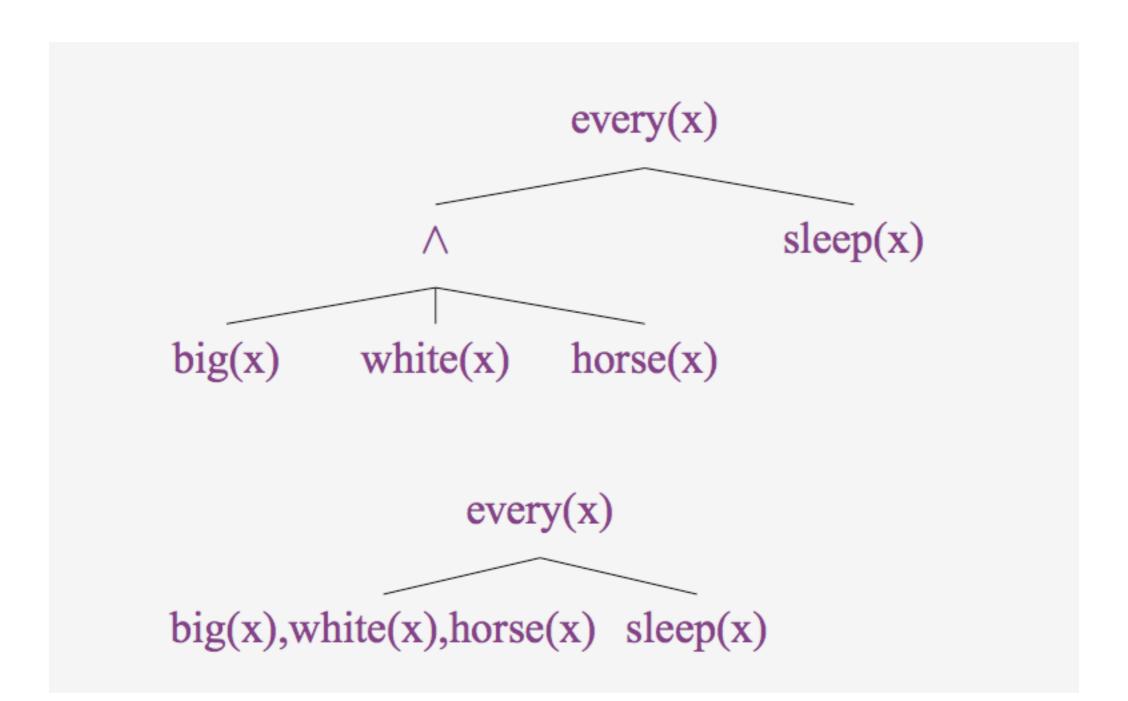

Working towards MRS (1/4)

• Every big white horse sleeps

 $every(x, \wedge big(x), \wedge (white(x), horse(x))), sleep(x))$

Working towards MRS (2/4)

Working towards MRS (3/4)

• And finally:

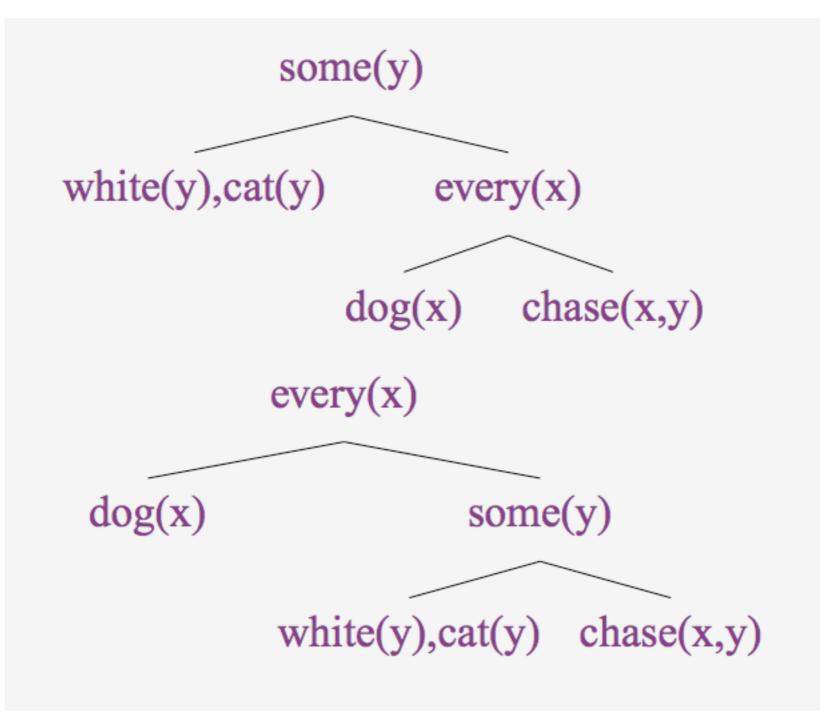

*h*0:every(*x*, *h*1, *h*2), *h*1:big(*x*), *h*1:white(*x*), *h*1:horse(*x*), *h*2:sleep(*x*)

Working towards MRS (4/4)

- This is a flat representation, which is a good start.
- Next we need to underspecify quantifier scope, and it's easier to see why with multiple quantifiers.
- At the same time, we want to be able to partially specify it, since this is required for adequate representations of NL semantics.

Underspecified quantifier scope (1/2)

• Every dog chases some white cat.

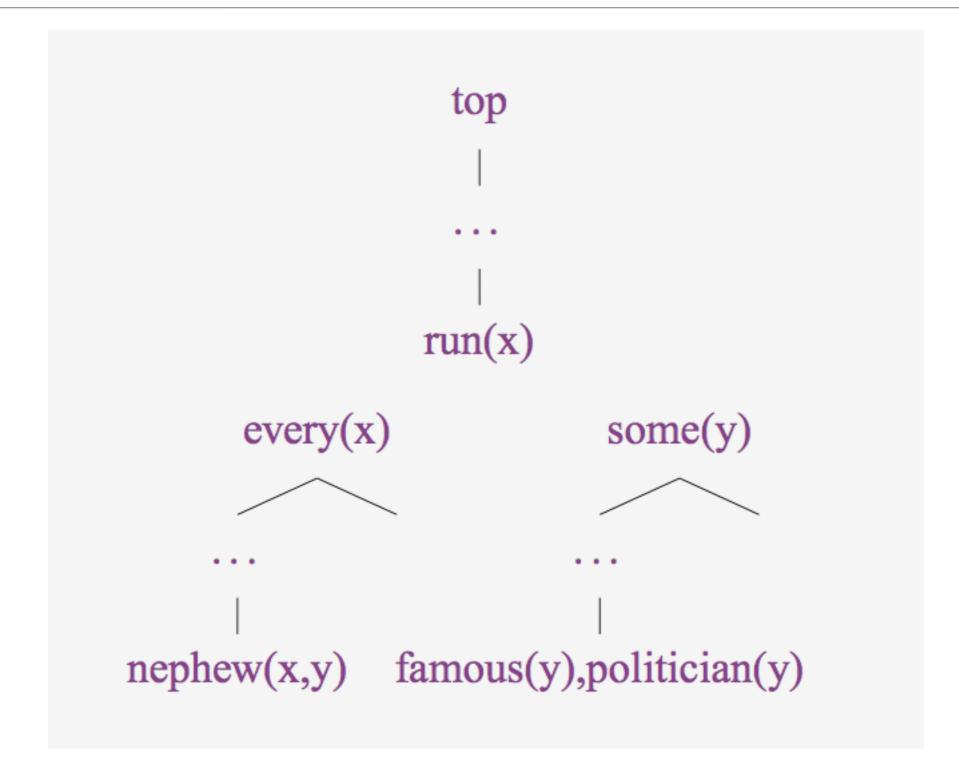

Underspecified quantifier scope (2/2)

- *h*1:every(*x*,*h*3,*h*4), *h*3:dog(*x*), *h*7:white(*y*), *h*7:cat(*y*),
 *h*5:some(*y*,*h*7,*h*1), *h*4:chase(*x*,*y*)
- h1:every(x,h3,h5), h3:dog(x), h7:white(y), h7:cat(y), h5:some(y,h7,h4), h4:chase(x,y)
- *h*1:every(*x*,*h*3,*h*A), *h*3:dog(*x*), *h*7:white(*y*), *h*7:cat(*y*),
 *h*5:some(*y*,*h*7,*h*B), *h*4:chase(*x*,*y*)

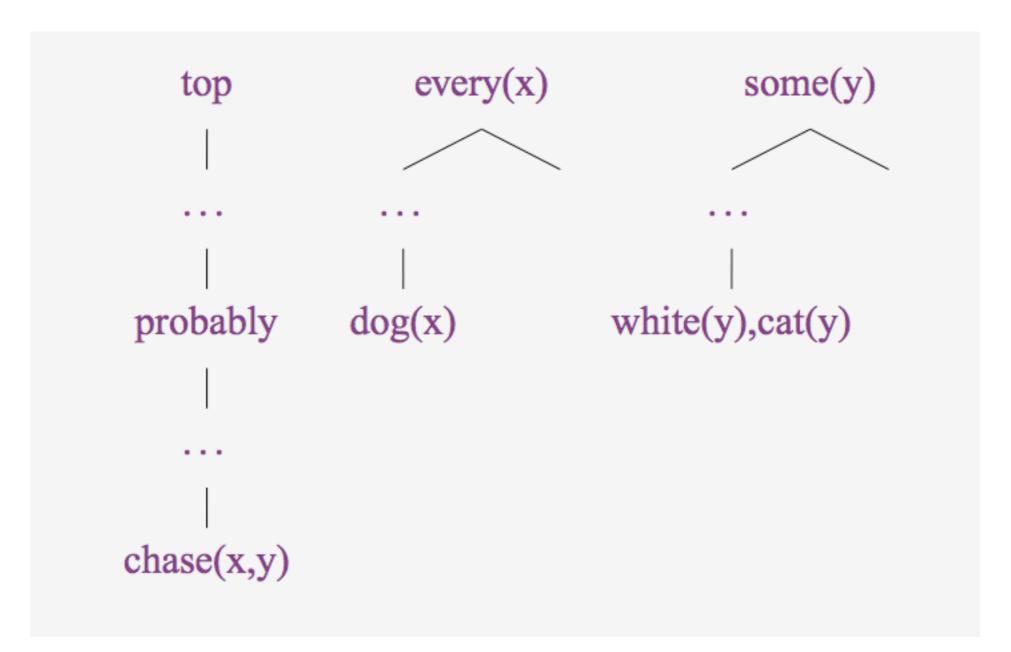

Partially constrained quantifier scope (1/4)

- For the BODY of quantifiers, we have no particular constraints to add.
- In turns out that the RESTRICTION needs to have partially underconstrained scope:
 - Every nephew of some famous politician runs.
 - every(x,some(y,famous(y) ^ politician(y), nephew(x,y)), run(x))
 - some(y,famous(y) ^ politician(y), every(x, nephew(x,y),run(x)))
 - But not:
 - every(x,run(x),some(y,famous(y) ^ politician(y), nephew(x,y)))
 - 'Everyone who runs is a nephew of a famous politician.'

Partially constrained quantifier scope (2/4)

Partially constrained quantifier scope (3/4)

 $\begin{array}{l} \langle h0, \{h2: \mathrm{every}(x, h3, h4), h5: \mathrm{nephew}(x, y), \\ h6: \mathrm{some}(y, h7, h8), h9: \mathrm{politician}(y), h9: \mathrm{famous}(y), \\ h10: \mathrm{run}(x) \}, \\ \{h0 =_q h10, h7 =_q h9, h3 =_q h5 \} \end{array}$

We've arrived at MRS!

- Flat structure
- Underspecification & partial specification of quantifier scope are possible

Linguistic Questions

- How do we build MRS representations compositionally?
- Is it linguistically adequate to insist that no process suppress relations?
- Under what circumstances do NLs (partially) constrain scope?
- Is it linguistically adequate to give scopal elements (esp. quantifiers, but also scopal modifiers) center-stage?

MRS in feature structures

- RELS: List (append-list) of relations
- HCONS: List (append-list) of handle constraints
- ICONS: List (append-list) of individual constraints
- HOOK: Collection of features 'published' for further composition: INDEX, LTOP, XARG
- ARGn: Roles within relations

Quick comparison to 566

- SWB RESTR = Matrix RELS
- SWB INDEX = Matrix HOOK.INDEX
- New here:
 - HCONS, ICONS
 - HOOK.LTOP, HOOK.XARG
 - C-CONT

Anatomy of an MRS

- An MRS consists of:
 - A top handle
 - A list of relations, each labeled by a handle
 - A list of handle constraints
 - (A list of individual constraints)
 - An (underspecified) MRS is well-formed iff the constraints can be resolved to form one or more trees (singly-rooted, connected, directed acyclic graphs).

Anatomy of a relation

- A relation has:
 - A predicate (string or type)
 - A label (handle)
 - One or more arguments: ARG0-n (ARG0 canonically being the event or individual introduced by the relation)

- The value of each ARGn is either:
 - An index, canonically identified with the ARG0 of another relation
 - A handle: identified with the label of another relation, the HARG of a handle constraint, or not identified with anything

Anatomy of a handle constraint

- Current sole handle constraint type: qeq
- 'Equal modulo quantifiers'
- Features: HARG, LARG
- → Unless some quantifier scopes in between, the value of this ARGn is the same as the label of that relation.
- When the label of a relation is the value of an ARGn, this corresponds to a branch in an MRS tree.
- When the value of an ARGn is qeq the label of a relation, this corresponds to a 'dotted' branch – i.e., a dominance relation.

When else are handles identified?

- Relations with the same handle value share the same scope.
- Typically, we see this with non-scopal modifiers (adverbs, adjectives, PPs) which share their handles with their modifiees.

Composition: Overview

- RELS and HCONS (and ICONS) on mother nodes
- HOOK, LKEYS
- ARGn <> indices
- ARGn <> handles
- LBL <> LBL
- Building *qeqs*

RELS and HCONS on mother nodes

- The RELS and HCONS (and ICONS) value of the mother is the append of the values from the daughter(s) and the C-CONT of the mother.
- C-CONT is the 'constructional content': allows phrase structure rules to introduce relations.
- Examples?
- From a semantic point of view, the C-CONT is just another daughter.

Semantic compositionality in action

```
basic-unary-phrase := phrase &
  [ STEM #stem,
    SYNSEM [ L-PERIPH #lperiph,
        R-PERIPH #rperiph,
        LOCAL [ CAT.MKG #mkg,
                CONT [ RELS.APPEND < \#r1, \#r2 >,
                       HCONS.APPEND < \#h1, \#h2 >,
                       ICONS.APPEND < \#i1, \#i2 > ] ],
    C-CONT [ RELS #r1,
             HCONS #h1,
             ICONS #i1 ],
    ARGS < sign & [ STEM #stem,
           SYNSEM [ L-PERIPH #lperiph,
                     R-PERIPH #rperiph,
                     LOCAL local &
                            [ CAT.MKG #mkg,
                              CONT [ RELS #r2,
                                     HCONS #h2,
                                     ICONS #i2 ] ] ] > ].
```

Now what?

- Phrase structure rules (and lexical rules) gather up RELS and HCONS from daughters.
- Phrase structure rules also (optionally) introduce further RELS and HCONS.
- How do we link the ARGn positions of the relations to the right things?
- How do we link the HARG/LARG of qeqs to the right things?

HOOK

- The CONT.HOOK is the information that a given sign exposes for further composition.
- By hypothesis, this includes only:
 - INDEX (the individual or event denoted by the sign, linked to some ARG0)
 - LTOP (the local top handle of the sign)
 - XARG (the external argument of the sign)

- The HOOK of a sign is identified its with the C-CONT.HOOK.
- The C-CONT.HOOK in turn is identified with the semantic head daughter, if there is one.
- Otherwise, the LTOP, INDEX, and XARG inside C-CONT.HOOK need to be constrained appropriately.

LKEYS

- The feature LKEYS houses pointers to important relations on the RELS list, most notably LKEYS.KEYREL.
- Only appropriate for lexical items.
- Serves as a uniform place to state linking constraints.
- Linking constraints: equality between HOOK.INDEX or HOOK.LTOP of arguments/modifiees and LKEYS.KEYREL.ARGn.

ARGn <> indices

SYNSEM.LKEYS.KEYREL.ARG1 #ind].

ARGn <> handles (1/2)

ARGn <> handles (2/2)

```
basic-determiner-lex := norm-hook-lex-item &
  [ SYNSEM [ LOCAL
     [ CAT [ HEAD det,
             VAL..HOOK [ INDEX #ind,
                          LTOP #larg ]],
       CONT [ HCONS <! qeq &
                      [ HARG #harg,
                        LARG #larg ] !>,
              RELS <! relation !> ] ],
       LKEYS.KEYREL quant-relation &
                     [ ARG0 #ind,
                       RSTR #harg ] ] ].
```

LBL <> LBL

isect-mod-phrase :=

head-mod-phrase-simple &

head-compositional &

[HEAD-DTR.SYNSEM.LOCAL.CONT.HOOK.LTOP #hand], NON-HEAD-DTR.SYNSEM.LOCAL.CONT.HOOK.LTOP #hand

- The rule for non-scopal modifiers identifies the LTOP of the two daughters, and thus the LBL of the main relation introduced by each.
- The HOOK value of the whole thing comes from the syntactic head, thanks to the type head-compositional.

Scopal modifiers (1/2)

```
scopal-mod-phrase :=
   head-mod-phrase-simple &
   [ NON-HEAD-DTR.SYNSEM.LOCAL
   [ CAT.HEAD.MOD < [ LOCAL scopal-mod ] >,
        CONT.HOOK #hook ],
        C-CONT [ HOOK #hook,
            HCONS <! !> ] ].
```

- No identification of LTOPs.
- Non-head (adjunct) daughter is the semantic head.

Scopal modifiers (2/2)

```
scopal-mod-lex := lex-item &
[ SYNSEM [ LOCAL [
CAT.HEAD.MOD < [ LOCAL scopal-mod &
                    [ ..LTOP #larg ]] >,
CONT.HCONS <! qeq &
                    [ HARG #harg,
                    LARG #larg ] !> ],
LKEYS.KEYREL.ARG1 #harg ]].
```

Builds qeq between its ARG1 and the MOD's LTOP

Building qeqs

- Determiners
- Scopal adverbs
- Clausal complement verbs (and nouns, adjectives, adpositions...)

Summary

- Phrase structure and lexical rules:
 - ... gather up RELS and HCONS (and ICONS)
 - ... potentially add further RELS and HCONS
 - ... unify elements on valence/ mod lists with signs

- ... pass up and/or modify HOOK information
- Lexical entries:
 - ... orchestrate the linking between valence/mod lists and the ARGn positions in the relations they contribute
 - ... expose certain information in the HOOK

Composition: Overview

- RELS and HCONS (and ICONS) on mother nodes
- HOOK, LKEYS
- ARGn <> indices
- ARGn <> handles
- LBL <> LBL
- Building *qeqs*
