# Lecture Schedule

(up to exam 2)

<b>21-Apr</b>	Mon	12	Specific Heats	18.4-18.6
<b>22-Apr</b>	Tues	13	Second Law	18.7-18.10
<b>24-Apr</b>	Thurs	14	Entropy	18.8-18.10
<b>25-Apr</b>	Fri	15	Charges	19.1-19.4
<b>28-Apr</b>	Mon	16	E field	19.5-19.66
<b>29-Apr</b>	Tues	17	Gauss law	19.7
<b>1-May</b>	Thurs	18	Electrical potential	20.1-20.3
<b>2-May</b>	Fri	19	Potential, conductors	20.4
<b>5-May</b>	Mon	20	Capacitors	20.5-20.6
<b>6-May</b>	Tues	21	Current	21.1-21.2
<b>8-May</b>	Thurs	22	Power, Series & Parallel Circuits	21.3-21.4
<b>9-May</b>	Fri		<b>EXAM 2 - Ch. 18,19,20</b>	

Minor revisions to calendar – almost caught up...

**Today**

# E field of a sheet of charge

- If a thin sheet carries **uniformly distributed charge** the E field will be **uniform and perpendicular** to the sheet

– For a sheet in the y-z plane, consider E field at a point on the x axis:

For contributions to  $\vec{E}$  from  $\Delta q$ 's symmetrically located at  $\pm y$

- x components add
- y components cancel

- Result: uniform E pointing out (if +q)
  - **Except near edges**: symmetry ends there!
  - “infinite sheet” approximation...
  - NOTICE: E does not diminish with distance!

Copyright © 2007 Pearson Prentice Hall, Inc.

- Field lines are parallel – same **density** everywhere

# Parallel oppositely charged plates = “capacitor”

- Consider 2 parallel (infinite) conducting plates, separation  $d$ , one has  $+q$  and the other has  $-q$
- In the gap, **E field is uniform** (constant magnitude and direction) and perpendicular to plates
  - Capacitors have many useful properties
    - important in physics and technology
  - We’ll come back to study them later

## Quiz 10

For an **infinite sheet** of charge:

How does the **magnitude** of the  $E$  field compare at the points shown?  
(field map shown is accurate)

- (A) All points have **different** field magnitudes
- (B) Field at **a** is larger, but other points are equal
- (C) **All points have equal field magnitudes**
- (D) Point **a** is smallest, but other points are equal
- (E) Cannot answer without more information.

## Last time

# Charging by induction

Charge separation by induction:

- Hold charged rod near metal object
  - (not in contact – no direct transfer of  $q$ )
- Rod's  $q$  attracts opposite charge within conductor
- same-sign charge is repelled – and left behind
- Conductor's net charge is still zero but E field of rod has caused charge separation
- Field set up between separated  $q$  inside conductor cancels external field from rod

The sea of electrons is attracted to the rod and shifts so that there is excess negative charge on the near surface.

The metal's net charge is still zero, but it has been *polarized* by the charged rod.

# Charging by Induction (2)

- Two uncharged metal spheres touch each other, forming a **single conductor**.
- Bring a **positively** charged rod near (but never touching) one sphere
- The + charged rod attracts electrons
- Induction:
  - Near sphere gets a net **negative** charge
  - Far sphere gets an equal net **positive** charge.
- Now **separate** the spheres:  
The near one has negative and the far one has positive charge.

# Induction via *Grounding*

- a) A single neutral conducting sphere is polarized by the positively charged rod, which attracts negative charges
- b) The conductor is **grounded** by connecting a wire to the Earth, which acts like a gigantic conductor
- c) Electrons from the ground neutralize the positive charge on the far face. The conductor is left negatively charged.
- (somewhere within the Earth there is a bit of extra negative charge)
- d) The negative charge remains if the connection to the ground is broken before the rod is removed.
- e) After the rod is removed, the sphere has a uniform negative charge.

# BTW: **E** fields can **polarize** insulators

In insulators, external charge's **E** field can distort the distribution of **electrons**, producing an asymmetry in the atoms that makes one end **+**, the other **-**. On average, there will be a net force on the object.  
(Notice the electrons do not **separate** from the nuclei, as in a conductor)

# Electric flux

- Michael Faraday (Britain, 1840s):

Electric forces are due to a “flow”, **electric flux**  $\Phi$

- **Superseded** by modern E field concept, but useful; flux can be connected to real physical quantities: we define  $\Phi_E = \vec{E} \cdot \vec{A}$
- **A** means area of a surface, taking into account its **angle** relative to the E field direction
  - What direction should we assign the vector?
  - The only **unique** direction wrt a plane is **perpendicular**
  - Define a **unit vector** normal (perpendicular) to surface, **n**
    - then  $\vec{A} \equiv A\hat{n}$

Deep thought: how do we choose which direction perpendicular to surface ? (we could reverse **n**)  
Here, we choose direction where E has a *parallel* component  
This will come up again...

Area vector  $\vec{A}$  is perpendicular to the surface. The magnitude of  $\vec{A}$  is the surface area  $A$ .

# Electric flux

- a) If  $A$  is **perpendicular** to  $E$ , then  $\Phi = EA$
- b) If  $A$  is **parallel** to  $E$ , then  $\Phi = 0$
- c) For other angles, the dot product gives:

$$\Phi_E = \vec{E} \cdot \vec{A} = E A \cos \theta$$

Copyright © 2007 Pearson Prentice Hall, Inc.

(c)

(a)

(b)

- For a **closed surface**, add up  $\Delta\Phi$  contributions from all **parts**
- for simple shapes it may be easy, otherwise use calculus

## Fluid flow analogy for flux

- Imagine air flowing through an area defined by a loop of wire: recall fluid flux =  $A v$ 
  - Maximum flow if loop is perpendicular to airflow
  - Zero if loop is parallel
  - At other angles, airflow is given by dot product of  $\vec{v}$  and  $\vec{A}$

$$\Phi_{AIR} = \vec{v} \cdot \vec{A} = vA \cos \theta$$

- Notice symmetry of dot product: we can say it is “(component of  $\vec{v}$  perpendicular to  $\vec{A}$ ) times  $A$ ”, OR “( $v$ ) times (component of  $\vec{A}$  perpendicular to  $\vec{v}$ )”

The air flowing through the loop is maximum when  $\theta = 0^\circ$ .

No air flows through the loop when  $\theta = 90^\circ$ .

$v_{\perp} = v \cos \theta$  is the component of the air velocity perpendicular to the loop.
