

Five Schott Glass Types

The following tables list the most important optical and physical constants for the five Schott optical glasses: BK 7, SF 11, LaSF N9, Bak 1, and F2. These are the materials used in most Melles Griot simple lens products and prisms. Index of refraction and transmission, as well as the most commonly required chemical characteristics and mechanical constants, are listed. Further numerical data on these glasses and a more detailed discussion of the various testing processes, can be found in the Schott optical glass catalog.

The index of refraction data was obtained by using the constants listed below together with the dispersion formula presented earlier (page A4.4). The constants were determined through the index of refraction measurements of a typical melt for each glass type. Note that the dispersion formula is only valid within the wavelength range

listed. It can be used to interpolate refractive index at other wavelengths within this range (to a precision of 1×10^{-5} or better), but should not be used to extrapolate to wavelengths beyond this range. Furthermore, keep in mind that the actual melt-to-melt tolerance on index of refraction is typically about ± 0.001 .

Internal transmittance values shown are melt-to-melt experimental means, and may be affected by thermal history (coating, annealing, or tempering operations) after manufacture.

For more detailed information of these materials, please refer to the Schott optical glass catalog.
