

# Roadmap

---

- Left over from Friday:
  - RNU2 locus
  - P element in large vs. small populations
  - Transposition machinery co-opted by cell
- Phylogenetic trees:
  - Interpreting a tree
  - Inferring trees by parsimony
  - Inferring trees by distance methods

From Liao (1999) AJHG

## Thought problem

---

- Cross P into a lab strain and maintain a population in bottles
- Population may live or die
- Which is likely to do better, a large or small population?
- *When this experiment has been done, large populations are more likely to survive*

## McClintock's “genome shock” hypothesis

---

- Transposons could allow an organism to control its mutation rate:
  - Suppress transposition when well adapted
  - Permit transposition when struggling, “hoping” for a useful mutation
- Alternative hypothesis: transposons are purely selfish
  - Suppress transposition whenever possible
  - Fail to suppress transposition when badly stressed
- Not easy to test these alternatives

## Finding a use for transposons

---

# Oxytricha genome rearrangement

---

- Two nuclei per cell:
  - Micronucleus used for reproduction, but genes not active
  - Macronucleus expresses genes
- Macronucleus genome is highly rearranged:
  - Cut into around 16,000 tiny chromosomes
  - Usually 1 gene per chromosome
  - Genes are re-assembled from fragments
  - Some are duplicated (dosage control?)
  - 95% of germline genome is destroyed

# Transposons harnessed to chew up genome

---

- Germline genome of *Oxytricha* full of transposons
- Macronucleus has none
- If transposases are inactivated, the macronucleus fails to develop properly
- Transposons and transposase probably central in rearrangement process

# What is a phylogeny?

---

- A branching tree showing inferred relationships
- Taxon, taxa: the units at the tips of the tree (species, populations, individuals, genes)
- Clade: all taxa descending from a common ancestor
- Root: the common ancestor of the whole tree

# What are phylogenies good for?

---

- Relationships between organisms, populations, species
- Dates of evolutionary events
- Evolutionary patterns—did some features evolve multiple times?
- Removing influence of phylogeny from ecological analyses (“comparative method”)
- Relationships among genes
- Patterns of speciation and diversification

## How to look at a phylogeny

---

- Branching pattern shows pattern of relationships
- Right-left ordering is NOT significant; can be rearranged to emphasize or obscure points!
- Branch lengths may or may not be meaningful
- Biologists draw root at the bottom; math and CS types draw root at the top

## Practice problem

---

Two of these trees are the same (except for branch lengths). Which two?

# Rooted versus unrooted trees

- A rooted tree (phylogeny) has a specific direction of evolution
- The root is the ancestral form from which the others evolved
- This is the most informative type of tree
- Unfortunately, most phylogeny inference methods produce unrooted trees

## Types of trees

Rooted trees reflect the most basal ancestor of the tree in question

Unrooted trees do not imply a known ancestral root.

## Rooted versus unrooted trees

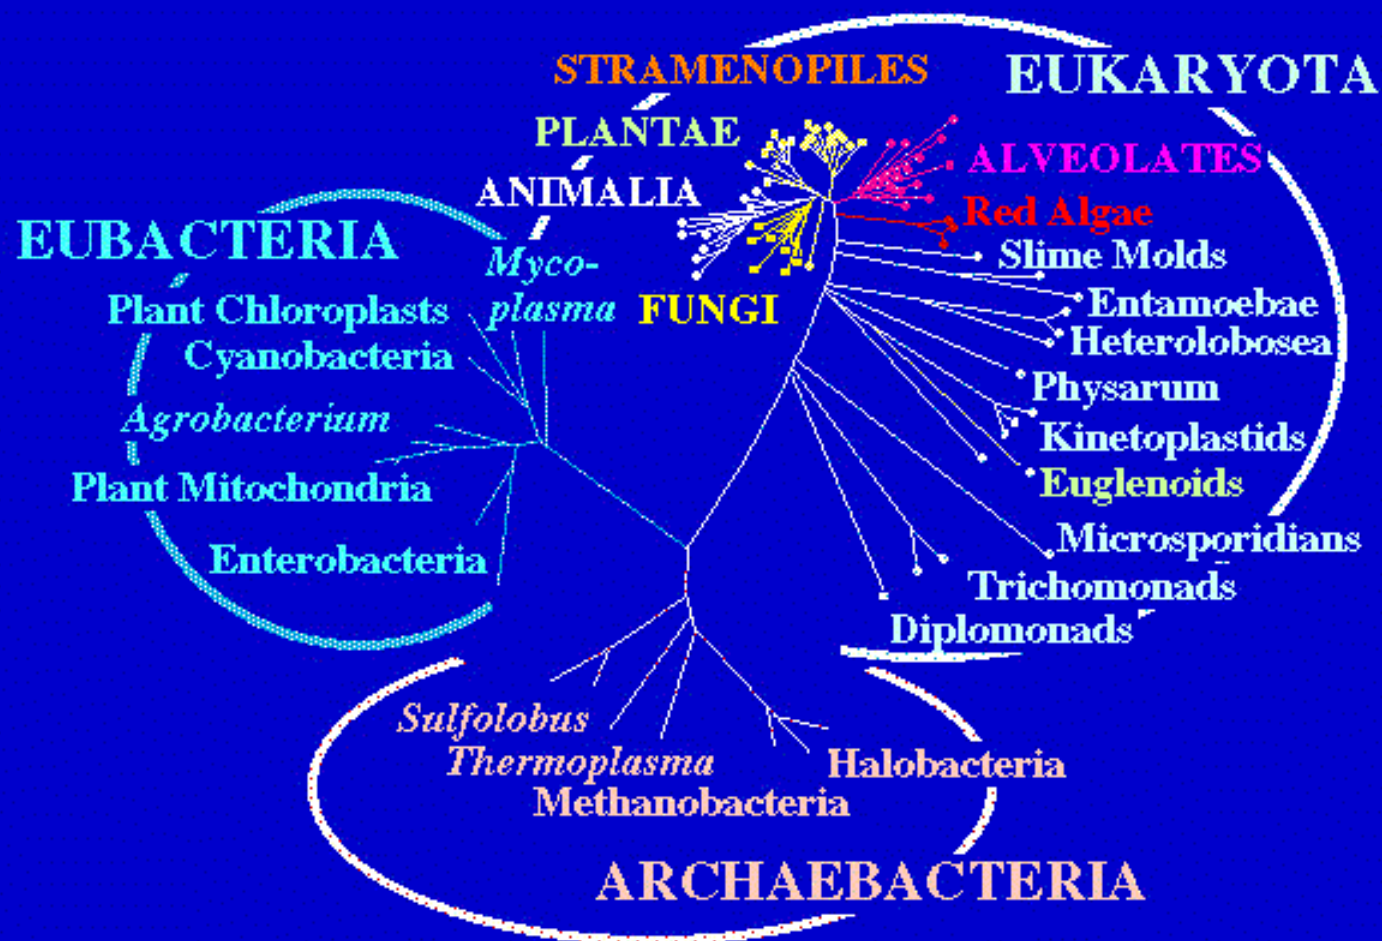

---

- An unrooted tree corresponds to a collection of different rooted trees
- We don't know the direction of evolution
- Biological interpretation can be difficult without root
- Ways to root a tree:
  - Outgroup
  - Molecular clock

# Outgroup rooting

- Outgroup – species known not to belong to clade
  - Wrong outgroup leads to wrong root
  - Too-distant outgroup leads to noise in data
- Some comparisons have no suitable outgroup

# Molecular clock

---

- Can we assume same rate of evolution everywhere (molecular clock)?
- If so:
  - Root is point most distant from all tips
  - Branch length is proportional to time
  - Dating any point on tree dates whole tree
- Clock may not hold:
  - Unequal generation time
  - Different selection constraints
  - Different mutation rates
- Clock assumption safest among closely related species

# Appropriate data for phylogenies

---

- Good phylogenetic data has:
  - Enough variation to show relationships
  - Not so much variation that it randomizes signal
  - Ability to establish homology
  - *Relative freedom from convergent evolution*
  - Mode of evolution relatively well understood
  - If possible, a good clock
- No one type of data works for all problems

## Some important dates in history

|                                    |                     |
|------------------------------------|---------------------|
| Origin of the universe             | -12 <sup>a</sup> ±2 |
| Formation of the solar system      | -4.6 ±0.4           |
| First self-replicating system      | -3.5 ±0.5           |
| Prokaryotic-eukaryotic divergence  | -2.5 ±0.3           |
| Plant-animal divergence            | -1.0                |
| Invertebrate-vertebrate divergence | -0.5                |
| Mammalian radiation beginning      | -0.1                |

<sup>a</sup>Billions of years ago

| Protein family          | PAMs <sup>a</sup> /100 res.<br>/10 <sup>8</sup> years | Protein Lookback time <sup>b</sup> |                        |
|-------------------------|---|------------------------------------|------------------------|
| Pseudogenes             | 400   | 45 <sup>c</sup>                    | Primates, Rodents      |
| Fibrinopeptides         | 90  | 200                                | Mammalian Radiation    |
| Lactalbumins            | 27  | 670                                | Vertebrates            |
| Ribonucleases           | 21  | 850                                | Animals                |
| Hemoglobins             | 12  | 1.5 <sup>d</sup>                   | Plants/Animals         |
| Acid Proteases          | 8   | 2.3                                | Prokaryotic/Eukaryotic |
| Triphosphate isomerase  | 3   | 6                                  | Archaea                |
| Glutamate dehydrogenase | 1   | 18                                 | ?                      |

<sup>a</sup>PAMs, point accepted mutations. <sup>b</sup>Useful lookback time, 360 PAMs, 15% identity. <sup>c</sup>Millions of years. <sup>d</sup>Billions of years.

# Convergent evolution?

- Why not use loci involved in “exciting” traits of the species?
- Convergent evolution:
  - Two clades are under the same external pressure
  - They independently evolve the same response
  - Not a reliable indicator of relationships
- Upper figure is many random genes; lower is a gene involved in fresh/saltwater adaptation

# Why phylogeny inference is hard

---

| Tips | Topologies |

# Why phylogenies are hard

---

- In many cases tree search known to be “NP complete”
- No efficient algorithm is known—none may exist but this is unproven
- Solving any NP-complete problem solves ALL OF THEM
- Four consequences of such an algorithm:
  - Reliably find the best phylogeny
  - Win USD 1 million (Millennium Prize) from Clay Institute
  - Crack most/all current codes (business and military)
  - Difficult conversation with the NSA....
- Must use heuristic approximations which will sometimes fail (get the wrong tree)

## Four major approaches to phylogeny inference

---

- Prefer the tree which—
  - Parsimony: explains the data with the fewest mutations
  - Distance: minimizes the difference between observed and expected distances between taxa
  - Likelihood: maximizes the probability of the data
  - Bayesian: maximizes the posterior probability of the data given a prior
- The first two are easier: given a correct mutational model the second two are likely more accurate

# Parsimony

---

- Prefer the tree which explains the data with the fewest events (mutations)
  - Does not use a model of the mutation process (so can't use the wrong one)
  - Implicitly assumes changes are rare
  - Applicable to wide range of data:
    - \* Sequences (DNA, RNA, protein)
    - \* Genome rearrangements
    - \* Morphological traits
  - Has issues if some branches are much longer than others

## Practice problem–parsimony

---

| Taxon | 1 | 2 | 3 | 4 | 5 |
|-------|---|---|---|---|---|
| A     | A | A | C | G | A |
| B     | T | A | A | T | T |
| C     | T | A | A | G | A |
| D     | A | C | C | G | T |

How many changes are needed on each tree topology?

Which topology is preferred by parsimony?

## Long branch attraction

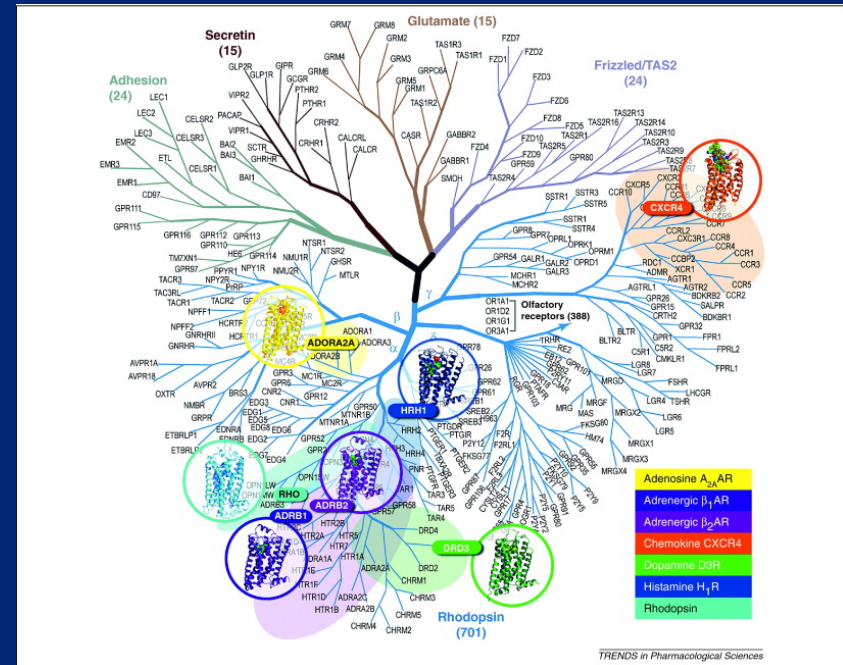

---

- When 2 changes on a long branch more probable than 1 change on a short branch, parsimony tends to group the long branches together
- This bias gets worse the more data you have (“inconsistency”)
- Discovered by Joe Felsenstein in this department

# Betting on your trees

- Ken Rice spent years making parsimony trees of G-protein coupled receptors
  - Maximum likelihood too slow
  - Distance methods didn't perform well
- If new gene groups with:
  - Odor receptors – ignore
  - Neurotransmitter receptors – spend \$2K to validate

*G-protein coupled receptor genes*

## Distance methods

---

- Transform data into a table of pairwise distances
- Find a tree which fits these distances well
- Different distance methods use different fitting criteria

|         | Human | Bonobo | Chimp | Gorilla | Orang |
|---------|-------|--------|-------|---------|-------|
| Human   | —     | 4      | 5     | 8       | 12    |
| Bonobo  | 4     | —      | 1     | 9       | 14    |
| Chimp   | 5     | 1      | —     | 8       | 14    |
| Gorilla | 8     | 9      | 8     | —       | 13    |
| Orang   | 12    | 14     | 14    | 13      | —     |

## Distance methods

---

- For very sparse mutations, counting differences may be good enough
- If some sites have mutated multiple times, this will undercount changes on the longer branches
- Use a mutational model to correct the distances
- Various models available:
  - Transition/transversion bias
  - Unequal base frequencies
  - Rate variation
  - Invariant sites

# UPGMA

---

- UPGMA (Unweighted Pair-Group Method of Analysis) is a simple distance method
- Seldom used today:
  - Assumes a molecular clock
  - Behaves badly if clock assumption violated
- Neighbor-joining is a non-clock version that is widely used:
  - Very fast
  - Allows use of a sophisticated mutation model
- UPGMA demonstrates the idea of distance methods in a simple way

## UPGMA rules

---

- Group together the two most similar species
- Divide their distance evenly across the branches leading to them
- Average their distances to all other species
- Rewrite the distance matrix with the new group and distances
- Repeat until tree is finished
- In case of ties, break arbitrarily or draw as three-way split

## UPGMA example

---

|   | A | B  | C | D  | E  |
|---|---|----|---|----|----|
| A | - | 5  | 1 | 8  | 9  |
| B | 5 | -  | 4 | 10 | 11 |
| C | 1 | 4  | - | 9  | 9  |
| D | 8 | 10 | 9 | -  | 2  |
| E | 9 | 11 | 9 | 2  | -  |

## UPGMA example

---

|   | A | B  | C | D  | E  |
|---|---|----|---|----|----|
| A | - | 5  | 1 | 8  | 9  |
| B | 5 | -  | 4 | 10 | 11 |
| C | 1 | 4  | - | 9  | 9  |
| D | 8 | 10 | 9 | -  | 2  |
| E | 9 | 11 | 9 | 2  | -  |

Group A and C to form AC, with branches of length 0.5

|    | AC  | B   | D   | E  |
|----|-----|-----|-----|----|
| AC | -   | 4.5 | 8.5 | 9  |
| B  | 4.5 | -   | 10  | 11 |
| D  | 8.5 | 10  | -   | 2  |
| E  | 9   | 11  | 2   | -  |

## UPGMA example

---

|    | AC  | B   | D   | E  |
|----|-----|-----|-----|----|
| AC | -   | 4.5 | 8.5 | 9  |
| B  | 4.5 | -   | 10  | 11 |
| D  | 8.5 | 10  | -   | 2  |
| E  | 9   | 11  | 2   | -  |

Group D and E to form DE, with branches of length 1.0

|    | AC   | B    | DE   |
|----|------|------|------|
| AC | -    | 4.5  | 8.75 |
| B  | 4.5  | -    | 10.5 |
| DE | 8.75 | 10.5 | -    |

## UPGMA example

---

|    | AC   | B    | DE   |
|----|------|------|------|
| AC | -    | 4.5  | 8.75 |
| B  | 4.5  | -    | 10.5 |
| DE | 8.75 | 10.5 | -    |

Group B with AC to form ABC, with branches of length 2.25

|     | ABC   | DE    |
|-----|-------|-------|
| ABC | -     | 9.625 |
| DE  | 9.625 | -     |

## UPGMA example

---

|     | ABC   | DE    |
|-----|-------|-------|
| ABC | -     | 9.625 |
| DE  | 9.625 | -     |

Group ABC with DE, with branches of length 4.80

## Two hazards of phylogeny

---

- Garbage in, garbage out:
  - Long pieces of autosomal DNA
  - Misaligned sequences
  - Non-homologous traits
- Gene tree not necessarily the same as the species tree
  - Paralogous
  - Incomplete lineage sorting (ancestral polymorphism)
  - Horizontal gene transfer

# Wednesday
